The TURNTABLE LATHE

WITH CROSS-SLIDING TURNTABLE

A MACHINE FOR MANUFACTURING

Hard, rapid, continuous manufacture. It has all the elements that such work requires: Solidly fastened stationary head. Cross-sliding flat, hexagonal turntable. Accurate and positive stop systems. Powerful all-geared drive, delivering the maximum power at all speeds. Massive construction, with weight distributed mathematically correct---fully 30 per cent. heavier than any similar machine. An unyielding and unwavering control combined with ease of manipulation and instant response to operating levers. A degree of accuracy and duplication that do away with all final bench fitting. A tool outfit that is universal in application to meet any manufacturing demands.

The MACHINE EVERY MANUFACTURER NEEDS. THE ONE ***YOU*** NEED.

One size. Bar capacity, 2½ x 26 in. Swing, 20 in. Belt or motor drive.
Equally efficient on forgings, castings or rod work.

Write for new catalog, "The Turntable Lathe," just off the press.

This Guarantee Goes With Every Vise: We fully guarantee all of our Vises to be satisfactory in every particular and will promptly replace, without cost, any parts broken or badly worn when such failures are due to faulty material or construction.

A 500 Kilowatt Westinghouse Exhaust-Steam Turbine, using exhaust steam from a 300 Kilowatt Simple Corliss Engine and a 100 Kilowatt tandem compound automatic engine in a certain small power station, is effecting a saving of 79 tons of coal monthly over previous rates of fuel consumption.

Westinghouse Exhaust-Steam Turbine Installation.

A feature in connection with the starting of this unit, showing its simple mechanical construction, was that the turbine was installed and placed in service by the company's own engineers, who, besides having never operated a Westinghouse Turbine, had never seen one in service, or even dismantled. The machine had operated a month before an erecting engineer reached the plant to make an inspection, which showed the turbine to be in excellent adjustment. Publication 9012 tells about our Exhaust-Steam Turbines.

Garvin Screw Machines

GIVE UNSURPASSED SATISFACTION

The best materials are used in manufacturing these machines. Parts made of Krupp Chrome Nickel Steel, Drop Steel Forgings and Vanadium Steel Springs. Absolutely no steel castings used. Machines can be realigned under all conditions of wear. Spindles are of large diameter, bearings are ground and run in bronze boxes. Cross-slides fitted with plug stops, capable of fine adjustment, and can be lifted from bed without removing turret base. Hexagon Turrets on all machines, except the No. 1. Independent stops to each of the six turret holes. Our turrets and slides have long been renowned for their rigidity without cumbersomeness, the result being large output. The turret momentum is stopped by a solid plug, the lock bolt being used for indexing only. Many other exclusive features.

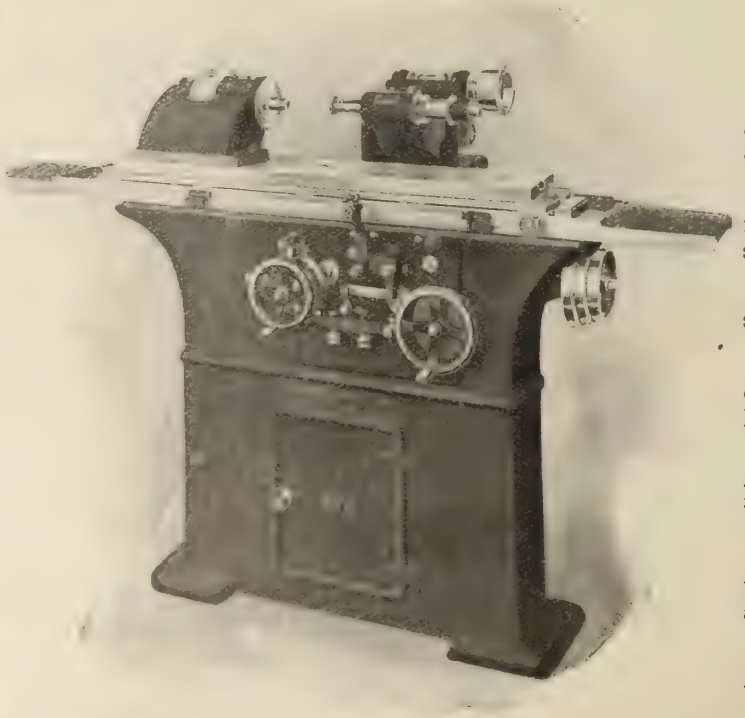
Williams & Wilson - Montreal

The Modern Internal Grinder, No. 6



This machine certainly

Does Cut Down the Cost

of internal grinding. It is full universal and, therefore, can do a great variety of work, both straight and taper.

This machine has our improved patented belt-tightening device, which prevents unnecessary strain on wheel spindle.

Give No. 6 a trial. It will prove itself.

CAPACITY AND DIMENSIONS

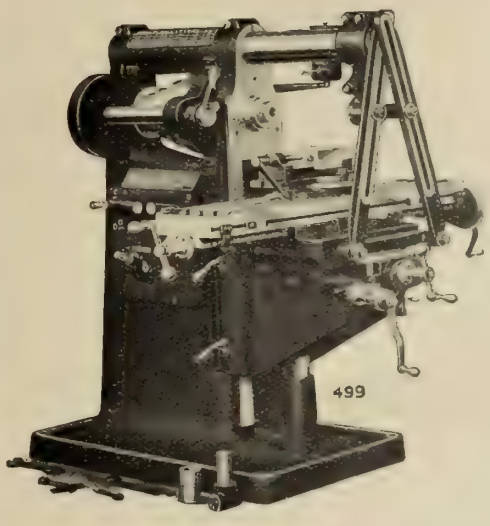
Will swing 10 in. diameter and grind 10 in. deep.

Extra long spindles may be obtained at small additional cost.

Speed of countershaft, 325 R.P.M.

Speed of wheel spindle, 8,000 to 12,000 R. P.M.

Countershaft driving pulley is 10 in. diameter by 4 in. face.



Weight, complete with countershaft, is about 2,200 lbs.

Floor space is about 36 in. by 72 in.

MODERN TOOL CO., Erie, Pa., U.S.A.

THE No. 2 CONE DRIVEN
CINCINNATI MILLER

OUR CONE TYPE MILLERS have not been forced off the market by Single Pulley Machines. And they will not be. We are making and selling more of them than ever before. We are able to do this because we keep our design ahead of all others.

The illustrations show the No. 2. It has the manufacturer's standard range:—

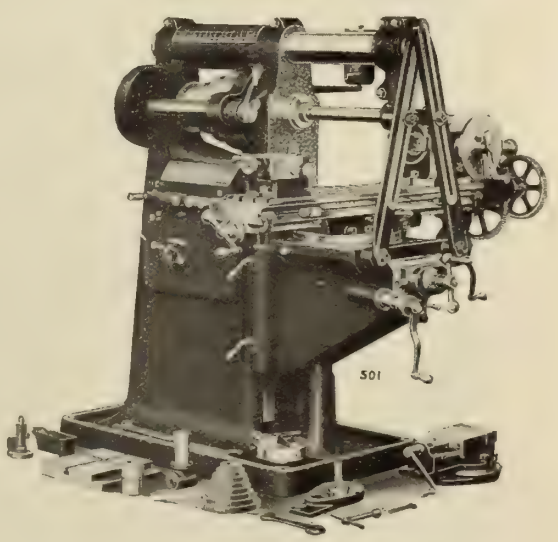
PLAIN— 28 in. x 8 in. x 19 in.
UNIVERSAL—25 in. x 8 in. x 18 in.

It can be supplied with power feed in one, two or three directions.

We call especial attention to the following features in its design:

The COLUMN is a complete box of rectangular form.

The FEED MECHANISM is a single unit, assembled by men who are specialists on this work.



When in place, it is an integral part of the machine.

It is high above the floor. The operator need not stoop to reach the levers.

The feed changes may be made within the practical limits of milling while taking a cut, without inconvenience or injury to the gears, because they are all hardened and run at moderate speeds.

The feed index is direct reading. It is the simplest index used on any machine tool.

All these features make this type the ideal machine for manufacturing small parts and for Tool Room use.

GET OUR COMPLETE CATALOG. ASK FOR PRICES AND DELIVERY.

Don't fail to mention adian Machinery" in writing to advertisers.

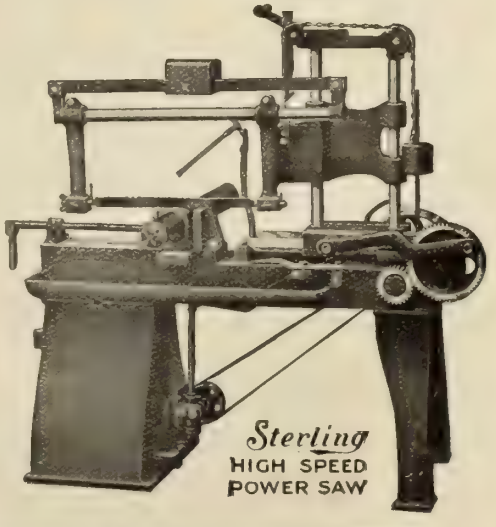
"Sterling" Hack Saw Blades

It is the universal custom at the beginning of the year to make new resolutions. This applies to business as well as social life. With the ormer we wish to deal.
f

It is the study of every manufacturer to devise ways and means by which to cut expenses. One large item of expense in the manufacture of many products is a Hack Saw Blade. Those who in the past have been using "STERLING" will look no further to effect economy in this direction, but for those who up to the beginning of the new year have not been users of the "STERLING" we would strongly recommend, as one of their business resolutions, to place a trial order for a Blade which, for many years, has been tried and not found wanting.

The remarkable success attained by the "STERLING" Blade is in a large measure due to the fact that the mill from which steel is procured that goes into its manufacture has a reputation second to none, and for uniformity of its product superior to any.

Added to the above fact, careful workmanship, particularly in the hardening process, prove by the most thorough and exhaustive tests that the "STERLING" has no equal and is in a class by itself.



"STERLING" Power Hack Saw Machines

These machines are known the world over for their efficiency and economy.

The Nos. 1 and 2 Machines are used for cutting small and medium size work.

The No. 3 Machine is designed to cut any size work up to and including 8 in. round or 8x12 in., and it is without question the most economical, fastest cutting and up-to-date Hack Saw Machine on the market.

When looking for a Hack Saw Machine, you can make no mistake in ordering a "STERLING."

The

Wright Wrench

CERTAINLY IS THE

Right Wrench

Just press the thumb and adjust instantly to any sized nut. Simple, practical, and a wonderful time-saver.

The adjustment is constant—it ***stays put.*** There is no spring or back-lash as in screw wrenches, so that it can neither slip nor get locked on a nut.

The Wright Wrench will do more work in less time than any other wrench, and will stand the hardest usage. It is especially good for night work, as it is adjusted with the hand that holds it, leaving the other free for handling the torch. It's splendid, too, for cold weather.

Used and endorsed by the Baldwin Locomotive Works, by master mechanics of several railroads, of a United States navy yard and of the Bell Telephone Co., and by hundreds of construction companies and machinists.

The Wright Wrench is made in the following sizes—6 inch, 8 inch, 10 inch, 12 inch, 15 inch, 18 inch. Also Automobile Wrenches in 8 inch and 10 inch size. Handles in all cases are drop-forged as part of bar.

Sample of the 10-inch wrench will be sent express prepaid to any point in Canada on receipt of $1.00.

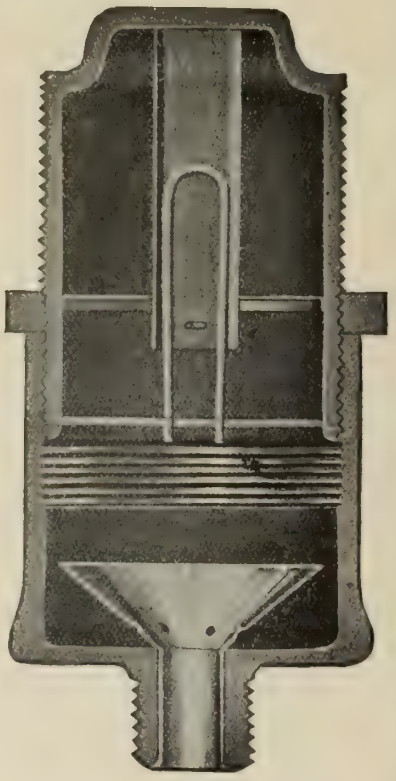
Manufacturers of The Philadelphia Grease Cup



For the Dominion of Canada

HERE'S THE CUP!

Here are some of the advantages of the

"Philadelphia" Grease Cup

First—The "**Philadelphia**" is guaranteed to save from 33 1-3 to 50 per cent. (with any standard grease) over any other system of lubricating machinery bearings.

Second—The "**Philadelphia**" is not a "new" grease cup. Several years hard service in all parts of the country under every condition, on all kinds of machinery has proved every claim made for them.

Third—The "Philadelphia" is the only automatic grease cup on the market in which compressed air is the feeding force.

Fourth—Because compressed air is used, the "**Philadelphia**" is the only cup in which the pressure is absolutely uniform from the time the cup is full of grease until the last drop is used.

Fifth—The pressure always being uniform is what guarantees that the consistency of the grease never changes in a "**Philadelphia**" cup. By this a saving which cannot be accomplished in any other cup.

Sixth—It is for these reasons that the "**Philadelphia**" cup is just as positive in action feeding up, down, horizontally, or in any position.

Seventh—Neither is the efficiency of the "**Philadelphia**" affected by centrifugal force when used on such positions as loose pulleys, etc.

Eight—The "**Philadelphia**" is absolutely dust proof.

Ninth—The engineer profits by the use of "**Philadelphia**" cups in the big saving of his time and labor, to say nothing of the attendant peace of mind as to the condition of his journals or the increased efficiency and decreased expense account he can show.

Tenth—"**Philadelphia**" cups appeal to the man who pays the bills because they are not only cheaper in first cost than spring or force feed cups, but effect a 33 1-3 to 50 per cent. saving in grease and cost of operation.

Sizes of Cups Manufactured—½-oz. 1-oz. 3-oz. 6-oz. Plain Steel and Polished.

MILLIONS WASTED

By Users of "Genuine" Babbitt

The high price of tin, which is controlled by manipulators, who can juggle the price up or down to suit their convenience, should cause users of "Genuine" Babbitt to consider seriously the advisability of adopting some cheaper, suitable substitute.

A "Genuine" Babbitt should contain about 88 per cent. tin. It is a notorious fact that tin is a very dry metal and it is by no means what it is claimed to be as a bearing metal, as its anti-frictional qualities are comparatively very poor. A "Genuine" Babbitt will not fill in the interstices and condition the shaft as Magnolia Metal does. Unless a "Genuine" bearing is kept flooded with oil it is liable to become hot and run out, whereas a Magnolia-lined bearing, under the same conditions, will more that likely run for years without any perceptible rise in temperature, on very scant lubrication. Unless a bearing metal is poured in a *separated condition* the weight of the shaft will rarely, if ever, cause it to squash. It is usually frictional heat that causes this trouble, to which "Genuine" Babbitt is very susceptible, and, therefore, it naturally follows that a high-grade, anti-friction metal like Magnolia is very much more dependable. Not only is Magnolia superior anti-frictionally, it will actually withstand 19 per cent. greater compression test than "Genuine" Babbitt. Thousands of practical users have made this discovery and are using Magnolia in preference to all other bearing metals.

Some years ago we had Dr. Torrey, Chief Assayer of the U. S. Mint, New York, test all the leading "Genuine" Babbitts then on the market. Every one of these Genuines ran out in from five to fifteen minutes under pressures ranging from 500 lbs. to 1,400 lbs. per square inch, whereas Magnolia ran at the same speed—1,600 revolutions per minute—for eighty minutes up to 2,000 lbs. per square inch, and came out of test in a perfect, highly-polished condition. It is very difficult to run the temperature of a Magnolia-lined bearing up to a destructive point.

Every civilized country of the world has contributed its quota of testimonials regarding the splendid results obtained from using Magnolia Metal. If you are using "Genuine," or any other bearing metal, we ask your careful consideration as to the merits of Magnolia. Magnolia is made of selected virgin materials of the best quality, which are still further cleaned, and graphite incorporated into it. Magnolia is idealic in all of the good qualities that go to make an all-around first-class bearing metal.

The Machine that does it

"SPOT WELDING" or Riveting Without Rivets

HOW IT'S DONE

- Take two pieces of sheet metal, lay one across the other on the lower die.
- Pull the lever arm shown on the head of the machine.
- This forces the upper die down until the metal is clamped between the upper and lower die.
- Touch the switch, and quick as a flash the weld is made.
- Lightning in a condensed form is what does it.
- The electricity goes through the sheet iron and fuses the metal at a point or spot the size of a rivet. Welds it right and tight.
- That's why it's called "spot" or "point" welding.
- NO PREPARATION OF STOCK NECESSARY.
- No projections or holes to punch,
- Saves the operations of punching and inserting rivets.
- BETTER AND STRONGER THAN RIVETING.
- We make over twenty different kinds of electric welding machines.

The Catalogue tells about them, and it's yours for the asking.

Modern Machine Tool Practice for Maximum Production

By Gordon C. Keith

The Past Few Years Have Seen Great Advances Made in Machine Tool Practice. The Whole Line of Machine Tools Were Re-designed so that High-speed Steels Could be Used to Their Full Capacity. It was then Necessary to Devise Equipment for Keeping the Machines in Operation the Greatest Percentage of Working Hours. In Other Words, it was Necessary to Cut Time Between Cuts. This Paper, Read Before the Central Railway and Engineering Club, Toronto, Dec. 20, 1910, Shows the Development of Machine Tools, and Also the Devices Designed in Order That Time Between Cuts May be Reduced to a Minimum and that Maximum Production May be Obtained.

Since the introduction of high speed steels and motor drive, there has been such a revolution in machine tool design that it is only now that the present status of machine tool practice may be definitely defined. A complete redesign of machine tools has been necessitated and all the changes made and new methods adopted have had the one object in view, viz. that of obtaining maximum production.

The starting point in obtaining maximum production has been the proper care of tools. In a number of Canadian shops it has been recognized, as it has also been in United States shops, that a central tool room with a man in charge is a large factor in securing maximum production. The shapes and sizes of lathe tools, boring cutters, chisels, the method of forging and treating the tools should be standardized as should also all shop equipment, clamping bolts, wrenches, etc. Even in the smaller shops, such as that of the Toronto Street Railway and other railroad repair shops, it has been found to pay to have one man grinding all the tools and have charge of the tool room. All carelessness with tools and ignorance in the selection of tools for certain work is eliminated by having the tools prepared and selected in advance, and kept in good shape, thus assisting in securing maximum production.

Probably the best illustration of a central tool room is that of the United States Navy Department, located at League Island, Philadelphia, Pa., for supplying the Atlantic Coast Navy yards. Standard chemical and physical specifications for high speed steel have been adopted. The plant has a capacity of 800 tools per day, and consists of a forge shop, treating department of chemical and physical test, together with the apparatus necessary for producing standard tools of the highest quality at minimum cost. Tools are made in such quantities as to ensure economical manufacture, and are carried in stock.

The apparatus necessary and the methods of using it as followed in the forging plant, are compiled on instruction charts, one of which is shown in Fig. 1. This covers the forging of straight round-nose roughing tools, right or left hand, giving the necessary dimensions and graphic instructions for using the applicances.

The enormous railway mileage in Canada and the United States has resulted in great advances being made in railway shop equipment and a statement of what is being accomplished with modern machine tools and high speed steels in the shops should prove of interest. A few years ago six pairs of car wheels per day was the maximum production. Machine tools have since been brought to a constantly high state of efficiency until the best lathes, of five years ago, averaged about twelve pairs per day. Within the past two or three years this output has been steadily increased by improvements in design and methods of handling until at the present time many railroads are equipped with lathes turning out from sixteen to twenty pairs of 36-inch standard make wheels in ten hours.

Record Production.

On May 11, 1910, a detailed record was kept on tire turning on a Niles-Bement-Pond wheel lathe at the West Albany shops of the New York Central & Hudson River Railroad. It will be noted in Fig. 2, that thirty-three pairs of 36-inch wheels were turned in 9 hours and 53 minutes, being an average of 17 minutes and 58 seconds per pair.

Wheel lathes were gradually increased in weight and power until it was finally found that the wheels and axles themselves were the weak point in the turning operation. Recognizing this fact Small & McNaughton brought out twenty years ago a design of a machine to overcome this difficulty. This lathe was at that time a radical departure from ordinary design. The turning of axles on centres was abandoned, the entire axle journal being received in the head by means of a split bush made to fit the axle and having its exterior turned taper. This eliminated the obvious weakness and hence springing of the centre and its projecting spindle. It held the axle rigidly close up to the wheel. The old form of wheel lathe was driven from one end and the power carried across the machine by a long shaft. This put an inevitable amount of torsion and lack of rigidity between the point at which the power was applied and the wheel to be turned at the other end of the axle, and it was found to be one serious source of vibration and chatter. So to overcome this difficulty the Small & McNaughton design was driven by a large spinal gear in the centre, having a gap through which the axle could be rolled. The power from the large central drive was furnished to each wheel through face plates. The outside spindles supporting the axle were also provided with face plates and chucks, hence the wheels were clamped rigidly between two staunch face plates driven from one and chucked by the other; thus the wheels were held with absolute rigidity and became, in fact, one with the machine itself.

On a modern wheel lathe no attention is paid to the hard skin of the tire caused by friction of the wheels and brake shoes, for the simple reason that the tool is put directly under this scale and a heavy roughing cut can be fed across in eight or nine minutes. After that, a finishing tool is used the full width and shape of the tire and fed directly in without any use of cross-feed, a third tool the shape of the flange finishing the operation. The increased output of modern lathes, comes from their great weight and power and improved facilities for handling and getting the wheels in and out of the lathe, and from the higher quality tool steel.

After the capacity of the wheel lathe got up to twenty or more pairs of wheels a day, the manual labor of clamping and unclamping the cutting tools became quite a serious matter for the operator, and a number of devices have been brought out to lighten and quicken this operation. The limit of human endurance comes into the problem and here clamping and unclamping, if it had to be done with a wrench on say twenty pairs of wheels per day, it would mean 350 to 400 manipulations in ten hours.

One device that has been brought out is in the form of a turret tool-holder which has the roughing and finishing tools set in it, the holder being rotated to bring the various forms into action.

Another device is a pneumatic clamp by which the operator simply opens a compressed air valve and clamps his tool by power. In this arrangement the air cylinder is built in the body of tool rest ; the piston carries a wedge which, operating between two rollers, forces up the long end of the clamping lever. Thus the operator is relived from several hundred strenuous muscular exertions leaving him more efficient to attend to the actual turning operations.

Sellers' 42-in. Car-wheel Lathe.

The Williams Sellers Co., Philadelphia, Pa., have developed a 42-in. car-wheel lathe, which illustrates what machine tool builders are accomplishing in the way of production in the railroad shop. It has been pointed out above, that a few years ago ten pairs per day was considered a good record. The rate has been constantly increased until an average of twenty minutes per pair has been obtained. This exemplifies the economies in railrod shop machine tool practice that have recently been brought about.

For the test of the Sellers lathe three pairs of 36-inch steel-tired wheels, selected at random from a large number shipped to the machine builders' plant by the Reading Railroad Co., were turned in an average of about 20 minutes per pair, including setting machinery and taking out of lathe. The actual time that the machine was in operation averaged about 18 minutes per pair, and 90 per cent. of the total time required represents the period that the machine was doing effective work.

The cut and feed during the test was $\frac{3}{8}$-inch each, taken at a speed of from 15 to 19 feet per minute. The time taken from floor to floor of a pair of wheels, as well as the other details of the test, are given in the following table :

	No. 1.		No. 2.		No. 3.		Engine truck whls.	
Diam. wheel finished	34⅜ in.		34 3-16 in.		34 11-16 in.		30⅝ in.	
Diam. Wheel rough	35½ in.		34 15-16 in.		34¼ in.		.....	
	Min.	Sec.	Min.	Sec.	Min.	Sec.	Min.	Sec.
Floor to chuck	1	5	2	6	1	18	1	2
Turning	17	8	16	2	18	17	13	55
Machine to floor	1	2	1	17		50		1
Total time	19	47	18	45	19	85	15	15
Cutting speed ft. min.	15 and		16	16		14		19

Time to change from turning tender to engine truck wheels, 6 min. 1 sec.

The operation of the machine during these tests was in the hands of William Anthony of the Reading shops of the Philadelphia and Reading Railroad.

In these tests the final finish was remarkably fine. There was not a trace of chatter to be found, and the surfaces of the treads were free from those fine cracks extending down into the metal that are so characteristic of surfaces from which metal has been removed in heavy cuts at high speeds. The reproductions of photographs of these surfaces taken first after roughing and then after the finishing cut, show the effect very clearly.

The method of procedure is the usual one. The wheels are set in position and the roughing tool made to take a cut across the tread and top of the flange. The tread and flange tool is then forced in, taking a broad smooth cut, and leaving the surface in excellent condition, already noted. Then comes a similar tool for cutting the taper at the outer edge of the taper and round the corner of the rim. This done, the wheels are finished.

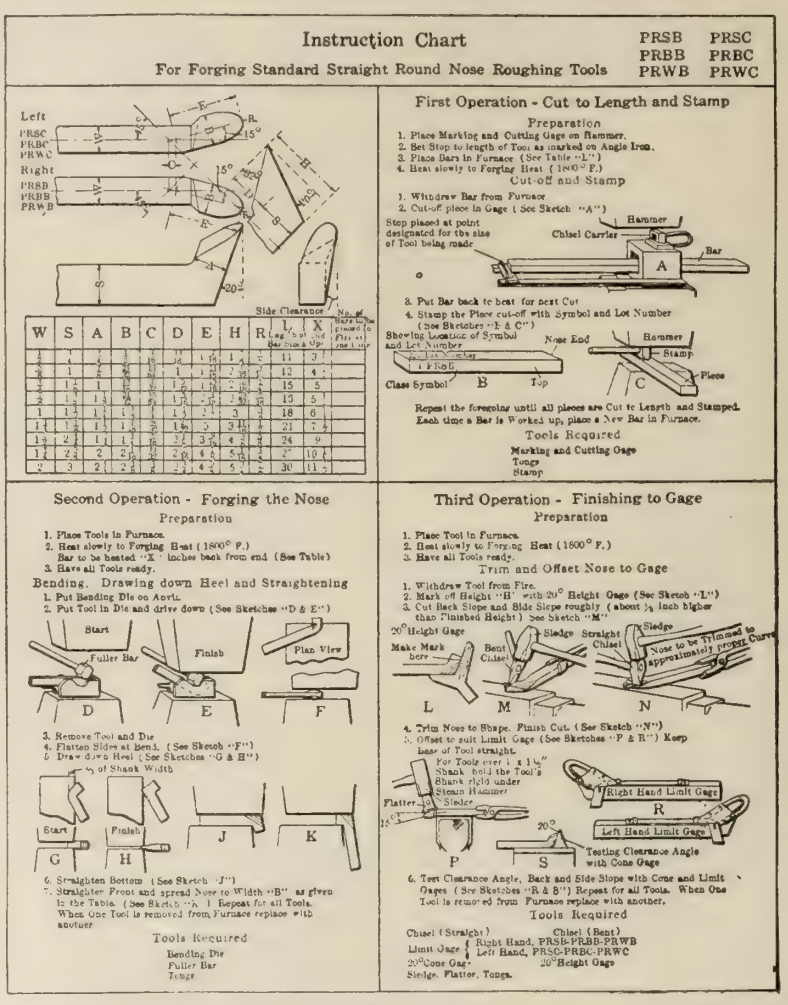

Fig. 1 Forging Instruction Chart used in Central Tool Department of U.S. Navy Yards.

The car wheel is driven by a motor set down on the extension of the bed. The lathe is an example of the application of individual motor drive to machine tools. Exhaustive tests have been made so that the machine tool builder has now no difficulty in selecting the proper power of motor for machining various materials for various combinations of speeds, feeds and depth of cut. Individual motor drive has been adopted in a large number of railway shops, machines of smaller capacities being arranged in groups and driven from a line shaft by one motor.

Sellers' Driving Wheel Lathe.

The high power wheel turning lathe for locomotive driving wheels shown in Fig. 9 is a result of the makers of machine tools trying to raise their capacities up to the cutting possibilities of high-speed steel. The lathe shown has

a swing of 90 inches. It is estimated that when the tool is cutting $\frac{3}{8}$ in. deep with $\frac{1}{2}$-in. feed the pressure at the point is about 55,000 lbs. Such a cut is readily made at a speed of 16 feet per minute, which requires 880,000 ft. lbs. per minute or nearly 27 h.p. at the point of the tool. To do this and avoid chattering the machine has been rigidly constructed. The device is obtained by means of dogs fastened at the rim or tire. The dog has a gripping shoe "A" shown in Fig. 11, and the pointed arm has a set screw "B". The arm swings up between the spokes of the wheel and the two grips come in line with the two faces of the tire. The set screw "B" is then turned in with a heavy wrench until its point has penetrated the metal and the shoe "A" has a firm grip. This shoe "A" is held in line and in place by the sides of the holding bracket, but the set screw "B" has a slight swinging motion. When the lathe is started, the shoe "A" drives the wheel through the tire, but if there be any slip the set screw "B" hangs back with the tire and in so doing gets out of alignment with "A". The slotted hole in the dog makes this possible, and as this lessens the distance between "A" and "B" the former is drawn into the metal of the tire, tightening the grip. When this grip exceeds the thrust of the tool, the tire will turn and the cutting proceed.

In testing the lathes, the cutting was limited to a speed of 13 ft. per minute, with a cut and feed of $\frac{1}{2}$-in., but it can be speeded to 25 ft. per minute and remove the same amount of metal, but the high speed steels will not stand the strain and heat. With a $\frac{3}{8}$ in. cut and $\frac{1}{2}$-in. feed the tool and the metal it is cutting, are at a red heat at the point of contact.

A demonstration was recently made in which the lathe was set complete for turning wheels of 78 inches diameter with $6\frac{1}{4}$ in. tires in 12 minutes, including the placing of the wheels in position for work. They were then finished complete in 19 minutes and placed on the floor in four minutes more. The total time from floor to floor, including the setting of the lathes, was 35 minutes. This work was the same as the turning off of a new set of tires and the cut was but $\frac{1}{8}$-in. deep.

In another test, a pair of 67 inch

Fig. 2—Table Showing Test of Niles-Bement-Pond Wheel Lathe.

wheels with 6½ in. tires, were chucked in 7 min., turning complete in 28 min., and put on the floor in 3 minutes more, or a total of 38 min. from floor to floor. In this case the cut was ⅝-in. deep.

A third test was made with 67 in. wheels and 6½ in. tires. They were chucked in 9 min. and finished in 43 min., the breaking of a tool having delayed the work four minutes. The work was done at a cutting speed of from 13 to 15 ft. per min. When a tool steel is produced that can stand the stress and heat of a higher speed no doubt there will be a greater output than modern machine tool practice will allow.

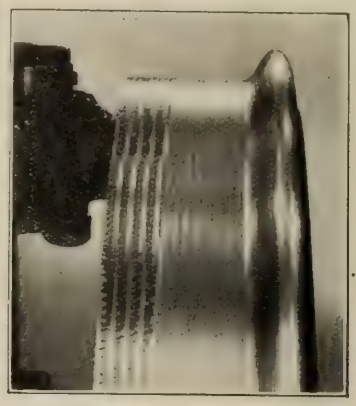

Fig. 7—Condition of Wheel at end of cut of Third Tool.

Landis Grinder.

Fig. 15 illustrates work done on the Landis Universal Grinder, which is built for use in the railroad tool room or repair shops. This grinder grinds reamers, gauges, dies and boring bars, does straight or taper, external or internal grinding and handles a large variety of grinding on small parts such as knuckle pins and cross head pins, link blocks and plates, parts of air valves, etc., with speed and accuracy. The Gap grinder is also a railroad tool, a gap along the bed adapting it to a variety of work and permits grinding accurately worms and racks. The operator standing directly in front of the table can manipulate it forward or back or longitudinally without moving from his position. Springing is eliminated, and the table is supported by a heavy bracket or knee underneath and an elevating screw as well, which it is claimed prevents the slightest spring. A very quick adjustment is obtained with this table. A large chip pan is provided at each end, as well as an oil groove running lengthwise at each side, arranged so that all the lubricant running into the chip pan at the farther end is drained back through a cored opening in the table to the pan nearer the supply tank.

Drills for Maximum Production.

At the convention of the American Railway Master Mechanics' and Master Car Builders' Associations at Atlantic City last June, The Colburn Machine Tool Co., Franklin, Pa., exhibited a heavy duty drill that was of unusual interest, not only because of its constructural features, but also by reason of the results in the way of rapid drilling which it makes possible. An improvement which tends to increase the usefulness of the tool is the new compound table.

As will be noticed from Fig. 15 this table is very different from the ordinary type and is a valuable adjunct to the machine. The table has a working surface of 16x30 in. and is provided with a rapid movement of 20 in. longitudinally and 8 in. transversely through

The machine is built on the unit system, that is, the speed changing mechanism is in one separate box, the feed change gears are enclosed in another separate case, and the head is a third unit entirely independent of the other parts.

In a series of tests made using Celfor high speed twist drills, cutting speeds as high as 200 ft. per min. in cast iron were obtained, although 125 to 150 ft. per min. were used in most cases, which was undoubtedly due to the fact that the nature of the work was the limiting factor rather than the drill or the machine itself.

Wheel Lathe.

Fig. 16 shows a modern 90 inch wheel lathe built by the London Machine Tool Co., Hamilton, and installed in the G. T. R. shops at Stratford.

The face plates are very heavy and massive, 91 inch diameter, and have bolted to them an internal gear of wide face and coarse pitch.

The construction of the drive is such

that the long bottom shaft is relieved to a considerable extent of the heavy torsion which invariably causes chatter on this class of machinery.

Clutches and change gears are provided, giving a wide range of speeds for all wheels from 31 inch to 81 inch on the tread.

The feed mechanism is of the link type, designed so as to give 8 impulses of feed per revolution of the face plate.

The bottom rests are moved along the bed by means of rack and pinion, and have extension to allow the cross rest to move in sufficiently close for small wheels.

The traveling head is the striking feature of this machine, and its great value is very apparent, especially on massive jobs where the work cannot be readily moved. This construction also makes it possible to do work requiring a great reach. This construction at first hand is criticised on account of the spring of head under heavy work. In actual practice this spring is found to be very small, owing to the fact that

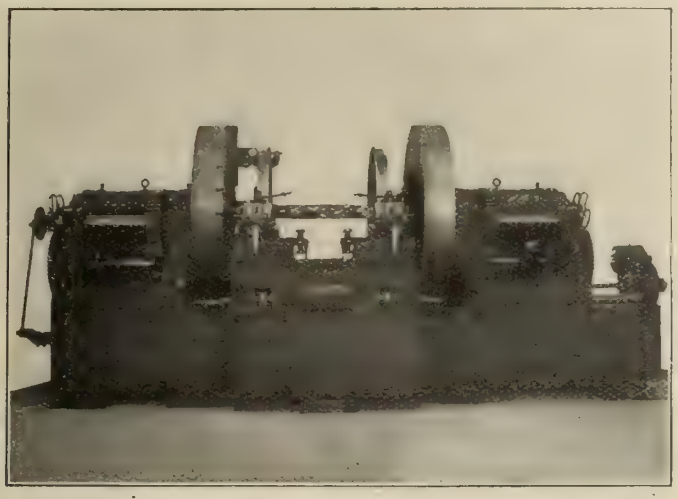

Fig. 9 Front Viewof Sellers' Wheel Lathe.

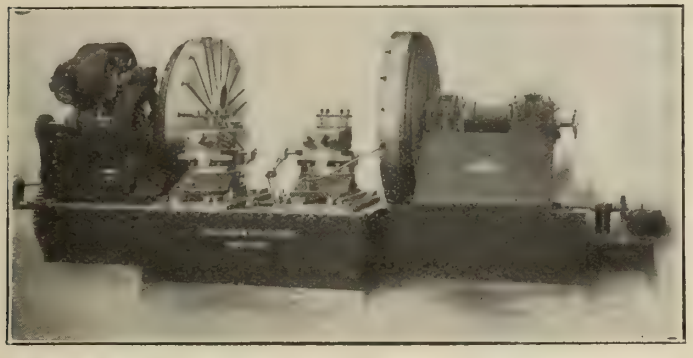

Fig. 16—90-in. Wheel Lathe, London Machine Tool Co., Hamilton.

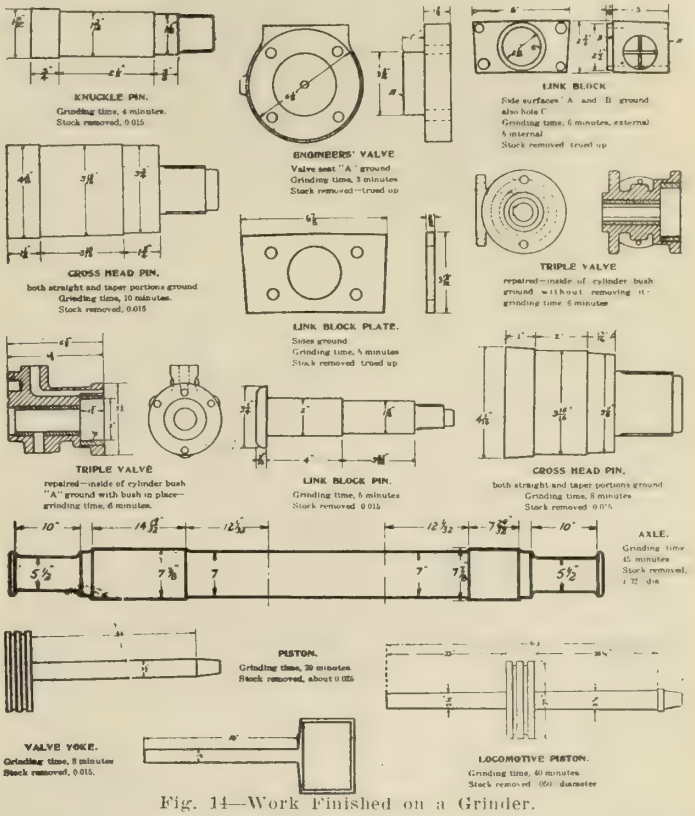

Fig. 14—Work Finished on a Grinder.

The rests are exceptionally massive, having power feed across the tread, varying from 4-25-in. per revolution to 12-25 in. per revolution.

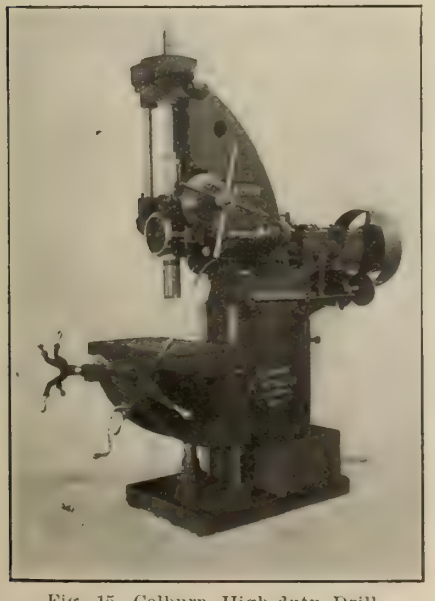

Fig. 15—Colburn High-duty Drill.

The left hand head is driven in and out by means of reversing pulleys acting through gears into a screw placed under the centre of gravity of head.

The drivers on this machine consist of four sets of adjusting steel blocks, having serrated edge gouging into the outside of tire. Powerful bolts are provided for slipping through the arm of the wheel, and drawing the wheel back against the face plate. This makes the wheel practically one with a heavy face plate, giving great rigidity. On a machine with this drive cuts 1 inch deep, and 7-16 inch feed have been taken.

Traveling Head Slotters.

In the design of the traveling head slotter, Fig. 17, the London Machine Tool Co. have taken of the experience of many of the largest users of slotters in the country, particularly in railroad shops where the heaviest service is required. Weak spots have been eliminated, many conveniences have been added, simplifications made in construction, and an excellent machine produced

the upward thrust is taken by two massive long bolts running clear through and anchored in base, and also the column is made very deep and heavy and the head being well scraped thereto makes spring practically negligible.

The quick power adjustment to head and table can be thrown in and out,

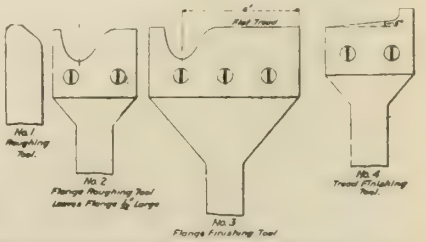

Fig. 13 Tools for Turning Tires on a Sellers Wheel Lathe.

while the head is running or standing, as desired. The quick power feature on certain classes of work means an increase of 200 p.c. in output. By this feature, as a general proposition, this machine will do 50 p.c. more work than was formerly possible. The quick re-

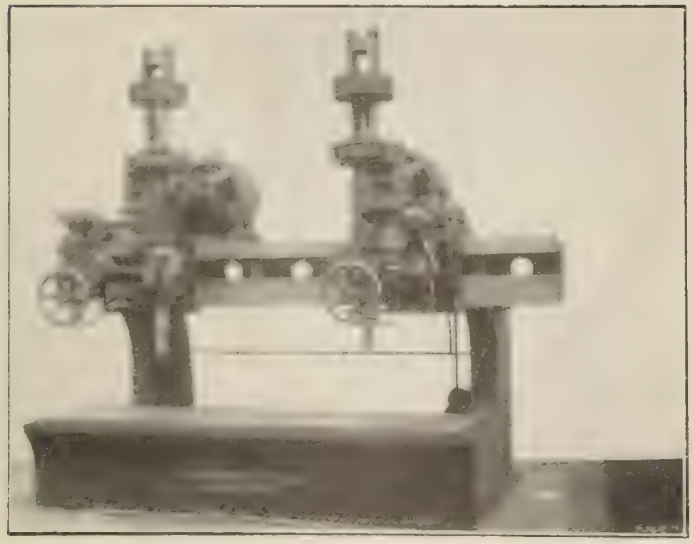

Fig. 21—Bertram 2-spindle Drilling Machine.

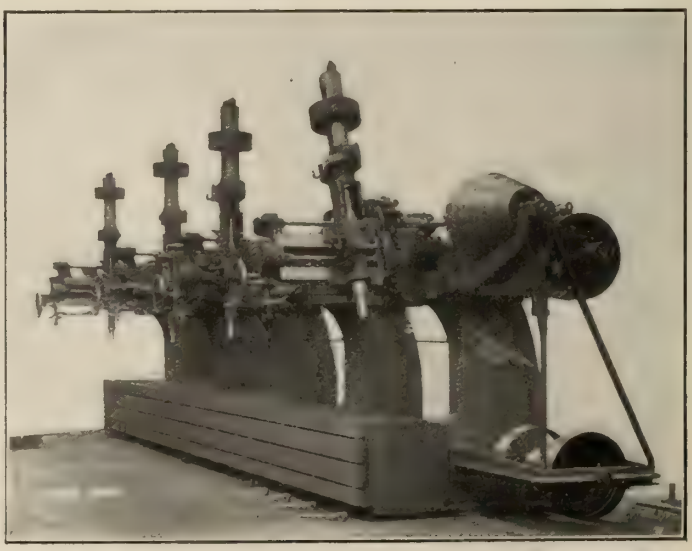

Fig. 22—Bertram 4-head Locomotive Frame Drilling Machine.

turn is of special construction giving remarkably even cutting strokes with very fast return. An indicator is attached showing amount of strokes.

The 42" coach wheel lathe shown in Fig 18 is designed by the London Machine Tool Co., Hamilton, for turning out railway coach wheels at a maximum rate.

The driving mechanism consists of two face plates, 56-in. diameter, and having open cut in same on one side, to admit of axle.

The centre head supporting the two internal gears, has a wide bearing on the base, and is secured to base by heavy bolts and dowels, making an exceptionally rigid construction. The method of taking insert is very simple,

there being merely two screws to loosen up, and the section driven out. On account of the shape of the gear ring it makes an exceptionally rigid construction, by which there is no vibration.

To the face plates are secured drivers of the latest approved form, giving ample driving capac'ty to the machine.

The tailstocks have spindles of large diameter, to which are secured very powerful self-centering chucks for gripping the wheels.

The heads are adjustable in and out for a distance of 12 inches, and are opened by means of screws operated by motors on each end. These motors do not require to be over 2 h.p. capacity each.

The cross slides and rest are extremely massive, and are provided with means for quickly releasing tool and securing it in position. 1½" x 3" tool steel should be used.

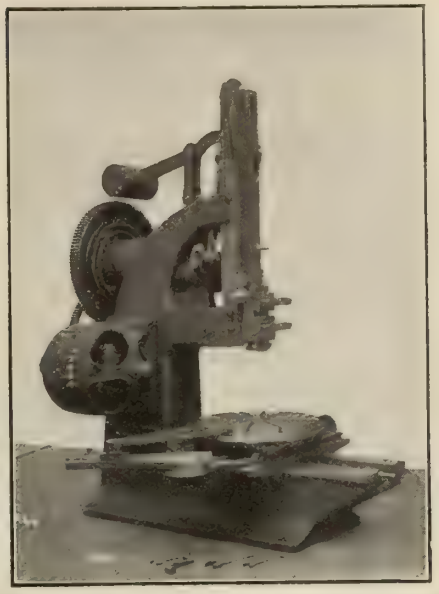

Fig. 23—Slotter Arranged for Machining Links

The feeds are 4 in number, and vary from 3-25ths to 12-25ths of an inch per revolution, which is ample for the work required.

The advantage of this machine is that the power is transmitted entirely through the gear, and bearing has only a steadying action—it has no transmitting function.

The heads are moved backwards and forwards by power which relieves the attendant of much incidental trouble.

The tool post is of a very powerful type, and is operated by large screw of coarse pitch and having differential threads and requiring a minimum of energy and friction.

Double Axle Lathe.

The double axle lathe shown on Fig. 19 is a very heavy and powerful ma-

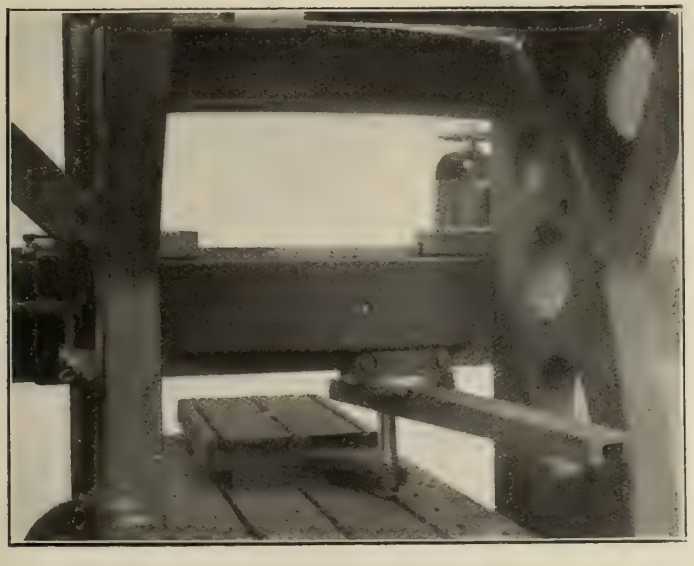

Fig. 24—Machining Links on a Planer.

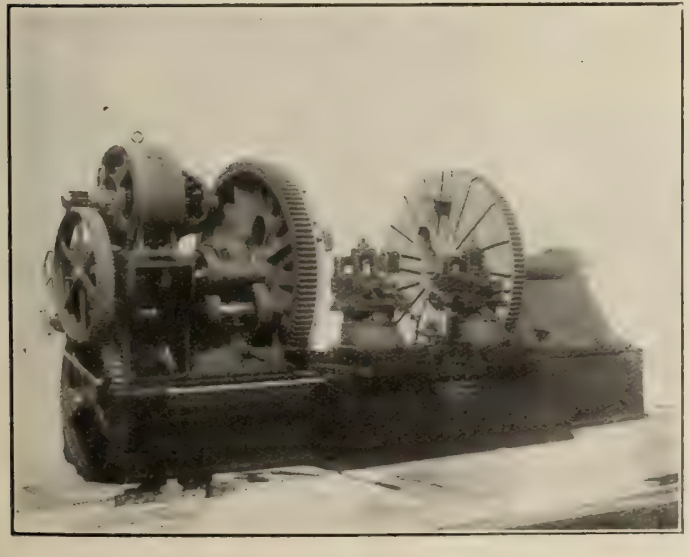

Fig. 26—Driving Wheel Lathe.

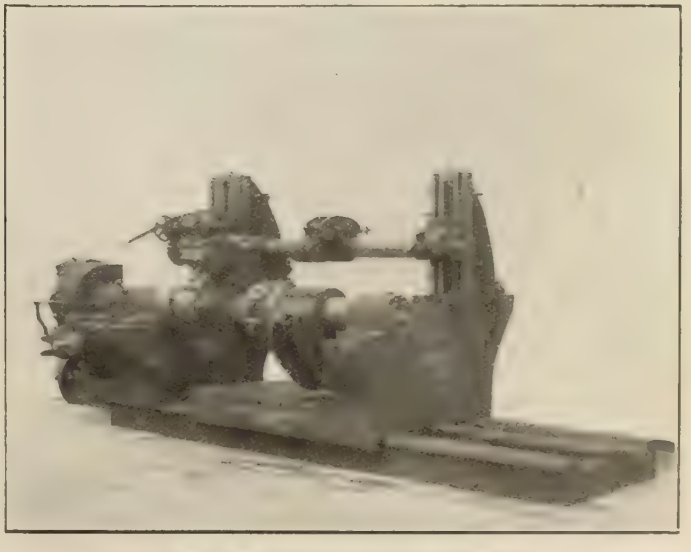

Fig. 28—Cylinder Boring Machine.

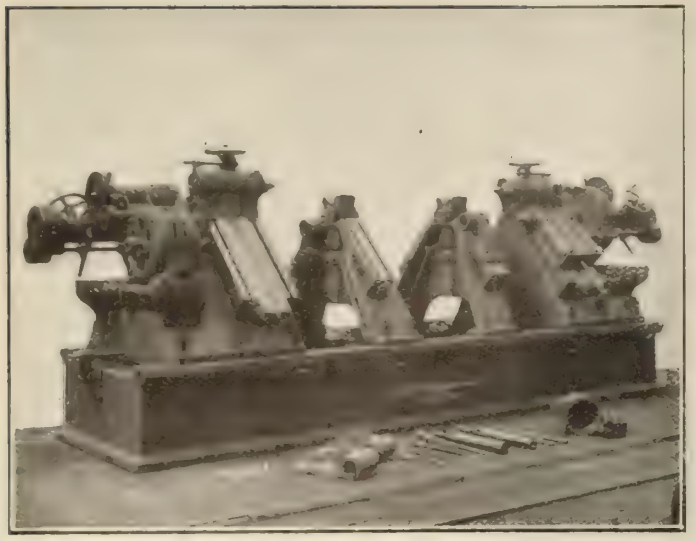

Fig. 29—Bertram Quartering Machine.

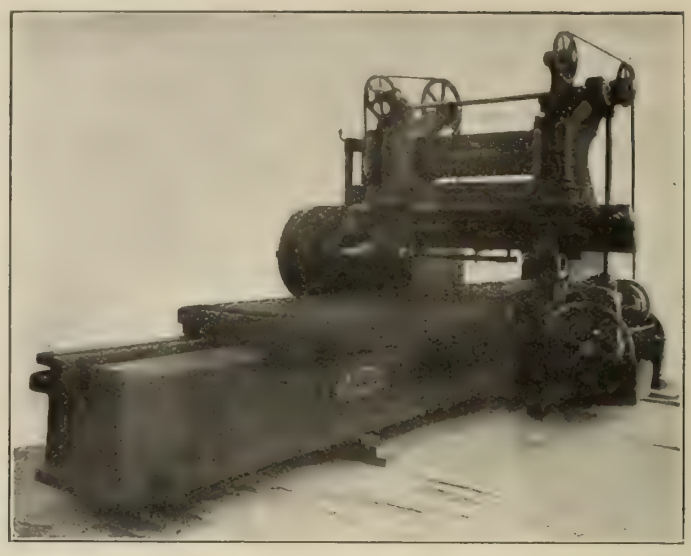

Fig. 30—Newton Horizontal Miller.

chine, designed for the rapid turning of car and locomotive axles.

The carriages are of the double type, having steel gearing and automatic throwout.

There are three changes of feed instantly obtained without stopping the machine. These feeds can be varied within wide range if desired.

The centre driving head has an opening of 13 inch diameter, and is driven by powerful gears of wide face and coarse pitch, and is provided with equalizing drivers.

For motor drive, a variable speed motor having a speed variation of 3 to 1, of from 15 to 30 h.p., depending on the class and quantity of work required, is used. If belt driven this machine is driven by a 6-inch belt, having 3 step cone of large diameter, cone being 24 inches.

Bertram Tools.

Fig. 20 shows a 30 inch double back geared high speed engine lathe, built by John Bertram & Sons Co., Dundas, for use in locomotive work. It admits 15 feet between centres. The swing is 32 inches over shears, and 20½ in. over the carriage. It is equipped with independent rod and screw feeds, power cross-feed, compound rest, plain tool block, quick change screw cutting gear from steel and two steady rests. It is driven by a 10 h.p. motor and has a speed of 400 to 600 r.p.m.

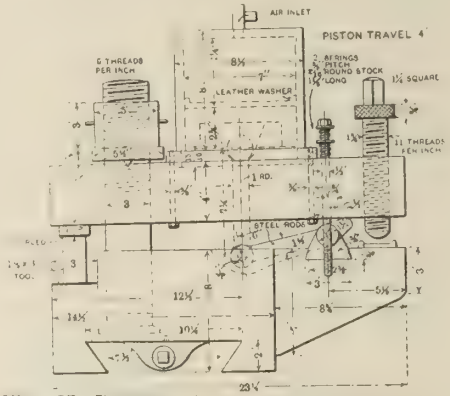

Fig. 27—Peterson Pneumatic Toolholder on Bertram Car Wheel Lathe.

The back gears are on the front of the lathe and are really front gears. It is therefore no longer necessary with such a lathe for a mechanic to turn the tool upside down on the back of the lathe to make a good cut. The front gears act directly on work giving smooth cut. This feature is typical of modern practice.

The two spindle drilling machines shown in Fig. 21 has spindles 3 inch in diameter, with 18½ in. traverse and three changes of speed. The heads are adjustable along the rail by hand or by power. The saddles are adjustable in and out 24 inches. The table is provided with a trough for collecting drill fluid which drains to pump for circulating. The range of spindle speeds is from 20 to 180 r.p.m. Heads and pump are motor driven.

Fig. 22 shows a modern four-head Bertram drilling machine such as used in the modern locomotive shop for drilling locomotive frames. Three heads are used for vertical drilling and one swivels for angular drilling. Power is transmitted to the head by driving shaft the entire length, which in turn is operated by a belted 20 h.p. constant speed motor driven countershaft at the end of the machine. Spindle ends are fitted for No. 5 Morse taper sockets.

Modern Method of Machining Links.

Two plans are adopted for machining reversing links. The Bertram slotter is shown in Fig. 23 and a planer attachment for giving the links the correct curve is shown in Fig. 24. The slotting attachment is used on a 12-inch heavy slotting machine. The table is 30 inch

Fig. 32—Newton Rod Boring Machine.

Fig. 31—Tabor Spiral Inserted Tooth Cutter.

in diameter with 30 in. longitudinal and 24 inch transverse speeds.

When used for slotting links the worm gear is unhitched and the table rotates. The device shown for planing links makes a perfect link. The construction of the jig will be readily seen from the illustration.

Fig. 25 shows a modern horizontal milling machine for milling the channels and plates on side rods. In the machine shown the distance between housings is 40½ in. The maximum distance from centre of spindle to table, 52 ins. Capacity to mill 14 ft. long. The spindle is 5½ ins. in diameter and has four changes of speed, fitted with taper socket 3½ ins. in diameter at its large end.

Bertram Driving Wheel Lathe.

Fig. 26 shows a 100 in. new model Bertram driving wheel lathe with a capacity for 86 inch wheels. The swing over the bed is 102 inches. Maximum distance between centres is 9 ft. Swing over the carriage is 96 inches. On the pedestals are mounted two compound rests with tool blocks fitted with a patent single screw tool holder. The feed mechanism gives four changes of feed to one revolution of drive. Driving pinions are steel cut from the solid. The face plates are provided with pockets, to receive crank pins and each is equipped with four Teas' Patent Sure-grip Drivers.

Tailstock or movable head provided with quick power traverse by 7½ h.p. motor. Carriages are of box construction and extend the full width of the bed so that pedestals carrying tool blocks will have sufficient travel for boring wheel centres. When turning full diameters the rear portion of the saddle is detached which will permit wheels being taken out of the machine without changing the position of the carriage, it being only necessary to remove the tailstock to the rear sufficient to withdraw the crank pins from the faceplate. It is motor driven by a 50 h.p. D.C. variable speed motor 500-100 r.p.m. with a 7½ h.p. A.C. constant speed motor for traversing the head.

The C.P.R. have successfully applied a pneumatic tool, designed by W. Peterson, of the C.P.R., Montreal, to Bertram lathes for turning car and truck wheels. In turning wheel tires it is necessary to change the tools three times for each tire and two men were required to operate the tools. With the tool shown, one man can operate them, the necessary champing and setting being accomplished almost simultaneously.

A two spindle Bertram cylinder boring machine is shown in Fig. 28. It has a bed 19 ft. 7 inch long, 48 inches wide and 10 inches deep on which is an adjustable table 57 inches long, 53 inches wide, having power traverse along the bed. When in working position it supports the outer end of boring bars, and when removed to the end of the bed the cylinder is free of the bars and may be lifted without taking the bars off the machine. The large bar is 12 inches in diameter having horizontal adjustment from 15 inches to 32 inches, and is 24 inches from centre of bar to top of table. The small bar is 5 inches in diameter, with horizontal adjustment of 14⅛ inches, also a vertical adjustment from 9 to 31 inches. Diameter of head on 12 inch bar is 21 inches; diameter of head on 5 inch bar is 11¼ inches. Each bar has three changes of feed. Machine has four facing heads, two for each bar, smallest to face 20 inches in diameter and the largest 44 inches in diameter. It is motor driven by 15 h.p. D.C. 2 to 1 variable speed motor.

Fig. 29 is a 100 inch locomotive driving wheel quartering machine. It has a capacity for wheels up to 90 inches in diameter on the tread, with from 10 to 20 inch stroke. The heads have long bearing on a substantial bed and are adjustable for axles of different lengths. These machines are built for either right or both right and left hand lead. Spindles are of large diameter and have 15 inch traverse. The saddles carrying same are graduated for easy adjustment to the desired stroke. Spindles have three changes of power feed and rapid hand movement. Axles are held on centres and on adjustable "V" bearings supporting by frames to which the wheels are securly clamped. The boring spindles are provided with outboard support and also with device for truing up crank pins. Each head is arranged with motor drive by a 5 h.p. constant speed motor.

Newton Machines.

The horizontal milling machine shown in Fig. 30 was built by The Newton Machine Tool Co., Philadelphia, for the G.T.R. shops, Point St. Charles, and is adapted to the milling of locomotive rods.

Installations of these millers at the Pittsburg works of the American Locomotive Co. show that they are slabbing rods on cuts from 14 to 18 inches wide, ⅜ to ½-inch deep, at a table feed advance of 8 inches per minute, and channeling two rods at one time, each channel being 3½ inches wide and 1¾ inches deep in one operation, at the rate of 2¼ inches to 2½ inches per minute. These results have been accomplished by means of the Tabor helical spiral inserted tooth high speed milling cutter, as shown by Fig. 31. The average removal of metal is equivalent to one cubic inch per minute of horse power.

Fig. 32 illustrates a new design of rod boring machine, with the additional adjustable support for the end of the spindles; when supported in this manner a cup cutter is used to trepan the rods. This view was taken in the Juniata shops of the Pennsylvania Railroad, and results show that 10½ inch diameter bores are made in rods 5-inch thick, in twenty (20) minutes, for which only a reaming cutter is necessary to finish. This method eliminates the necessity of drilling a pilot hole. Both holes are finished at the same time.

Cut Time Between Cuts.

In a recent address on shop efficiency given by E. P. Bullard, president of the Bullard Machine Tool Co., Bridgeport, Conn., he summed up the problem of reducing shop costs in the following terse sentence. "To cut shop costs, cut the time between cuts."

As an example of the inefficiency resulting from not cutting time between cuts, he pointed out that in a prominent shop, after a difficult piece of work had been finished on a boring mill, it was necessary to wait from 10 a.m. to 3 p.m. before a new forging was available, the machine in the meantime lying idle. He also pointed out that a great deal of time is wasted in boring mill operations in adjusting the machine to the exact size required by the work and stated that a considerable time can be saved on machines equipped with micrometer dials which permit instant and accurate adjustment.

W. R. Towne, president of the Yale & Towne Co., Stamford, Conn., states that by the use of scientific methods and automatic machinery, his company, within the past six years, had achieved increased output, decreased labor cost and increased wages to employes.

In speaking with a superintendent of a large Hamilton plant recently he stated "Deliver tools to the men. Keep men busy. More time is lost in men looking for work than in actual production." In the G.T.R. shops, Stratford, this has been recognized, and in order that men may be kept busy, chasers have been appointed to keep the men supplied with the work. At first the men looked on the innovation with disfavor, but now they keep the chaser busy with requests for more work.

With the development in machine tools and improved methods between operations, greater shop production is made possible. The foregoing by no means exhausts modern practice, but it points out a number of main features and describes a number of interesting tools now found in the machine shop. Various attachments and special machines have also been devised. Perfection is a hard thing to obtain, but manufacturers of machine tools, master mechanics, shop foremen and managers are on the right track, and with the progress that is being made it may not be very long before still greater outputs will be possible.

Experiments on Water Discharge from Short Nozzles

By James Barr, B.Sc., and George Fax *

The Results of a Series of Tests Conducted at the Canada Foundry Co., Toronto, by George Fax, Have Been Taken up by James Barr, and Some Very Instructive Inferences Drawn Therefrom. While the Treatment of the Subject is Largely Mathematical, the Forceful Manner in Which it is Placed Before the Reader Simplifies any Difficulties That Might Otherwise Arise. The Mathematical Deductions Involved are Such as Arise in the Routine of Every Engineer who Attempts to Understand his Indicator Cards. In Addition, it Might be Said That the Advent of Water Wheels in Such Large Numbers Makes This Article Doubly Interesting as Adding to the Fund of Useful Hydraulic Information.

IF we have two variable quantities (x and y) connected by an equation of the form $y=Ax^n$, where A and n are numerical constants, we shall obtain a straight line if we plot a graph showing the logarithms of x and y; and from the position and slope of this line we can readily find the values of A and n.

This device is often of great practical service, not only in obtaining the values of A and n, but also in showing graphically the true relation between the varying quantities x and y, since the straight line can often be easily and accurately drawn.

For example, it is generally supposed that if D be the discharge from an orifice, and H the head or pressure at the orifice $D=A H^n$ where A and n have approximately constant values.

Deductions.

The accompanying table and diagram indicate the method of plotting the results and deducing the equations.

Let D be the discharge in Imperial gallons per minute and H the head or pressure at the nozzle in pds. per sq. inch. We see from the table that the values of D range from 37 to 364, and therefore log D varies from log 37 (=1.568) to log 364 (=2.561). The values of H range from 30 to 200, and therefore log H varies from log 30 (=1.477) to log 206 (=2.300).

We accordingly lay off a horizontal scale ranging from 1.5 to 2.6 and a vertical scale ranging from 1.4 to 2.3. We can now readily construct logarithmic scales of D and H. The log of 100 is 2, so the value 100 (of D or H) will appear opposite the point 2 in our scales. Similarly log 140=2.146 and the value 140 will, therefore, appear at the point 2.146 on our scales. In this way we find as many points as we deem sufficient to complete the scales. The experimental results are now plotted in the usual fashion. For instance, at a pressure of 100 lbs. per sq. inch, the ¾ in. nozzle was found to discharge 121 gallons per minute. Through the point 100 on the H scale we draw a horizontal line to meet a vertical line through the point 121 on the D scale, and the point of intersection P, is a point on the curve for the ¾ in. nozzle.

When all the points are plotted the nearest straight lines are drawn through them. The equation to each of the straight lines is deduced in the following way:

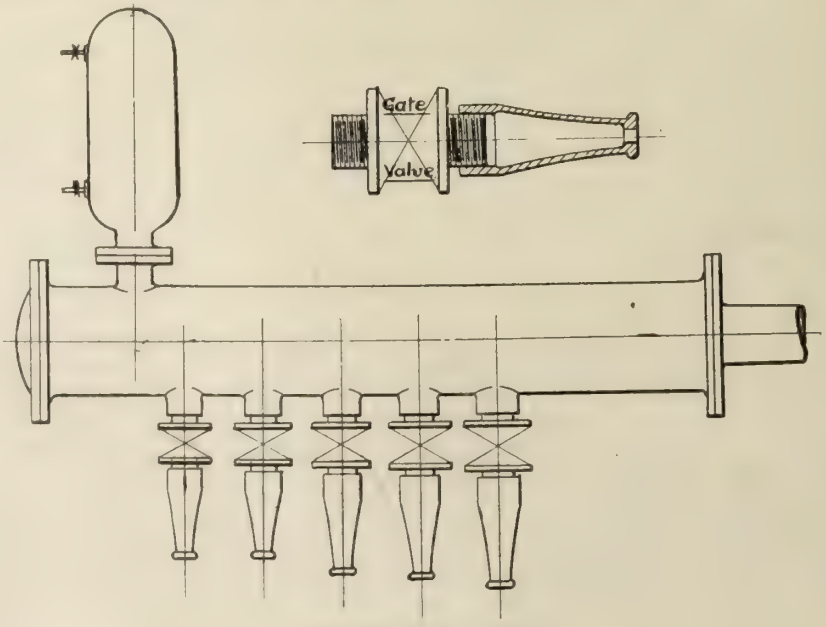
If $D=A H^n$

$\log D=\log A+n \log H$.

Log A is a constant quantity and n is, in the diagram, the tangent of the angle which the line makes with the vertical axis. Considering point P

$$n=\frac{PQ}{QR}=\frac{7.8}{15.6}=\frac{1}{2};$$

log D=2.083; and H=2; therefore we have from the equation,



$\log D=\log A+n \log H$;

$2.083=\log A+\frac{1}{2}\times 2$; or

$\log A=1.083$; therefore

$A=12.1$.

Therefore, $D=12.1 H^{\frac{1}{2}}$ is, very approximately, the equation to the line.

Apparatus Used in Test.

For any value of H, within the limits of the line, we can find D from this equation,

If H=166;

$D=12.1\sqrt{166}=12.1\times 12.9=156$.

which is the value given by the graph.

In the equations given in the diagram, D is the discharge in Imperial gallons per minute, and H is the head at the orifice in pds. per sq. inch. The diagram also shows a scale of discharge in U. S. gallons per minute, and a scale of heads in feet of water. These are easily constructed as follows:

Taking N. Imp. gall.=(1.2N) U.S. gal.=M. U. S. gal., we have log M=log 1.2+log N.=0.079+log N.

Therefore, if, on our logarithmic scale of Imp. gallons we add to any value N a distance equal to 0.079 on our scale of logarithmic we shall arrive at the corresponding value M of U. S. gallons. For example, if N be 100 in Imp. gal., we see this number is at 2.0 on our original scale of logarithms, and opposite the reading 2.079 on the scale we find 120, which is the corresponding value M in U. S. gals. In other words, the U. S. gal. scale is obtained by moving the Imp. gal. scale forward through a distance 0.079 on our scale of logarithms. This has been done on the diagram by moving the scale this distance to the left, and placing it at the top of the diagram, to avoid confusion. It will be seen that 120 on the U. S. scale is vertically above 100 on the Imperial scale.

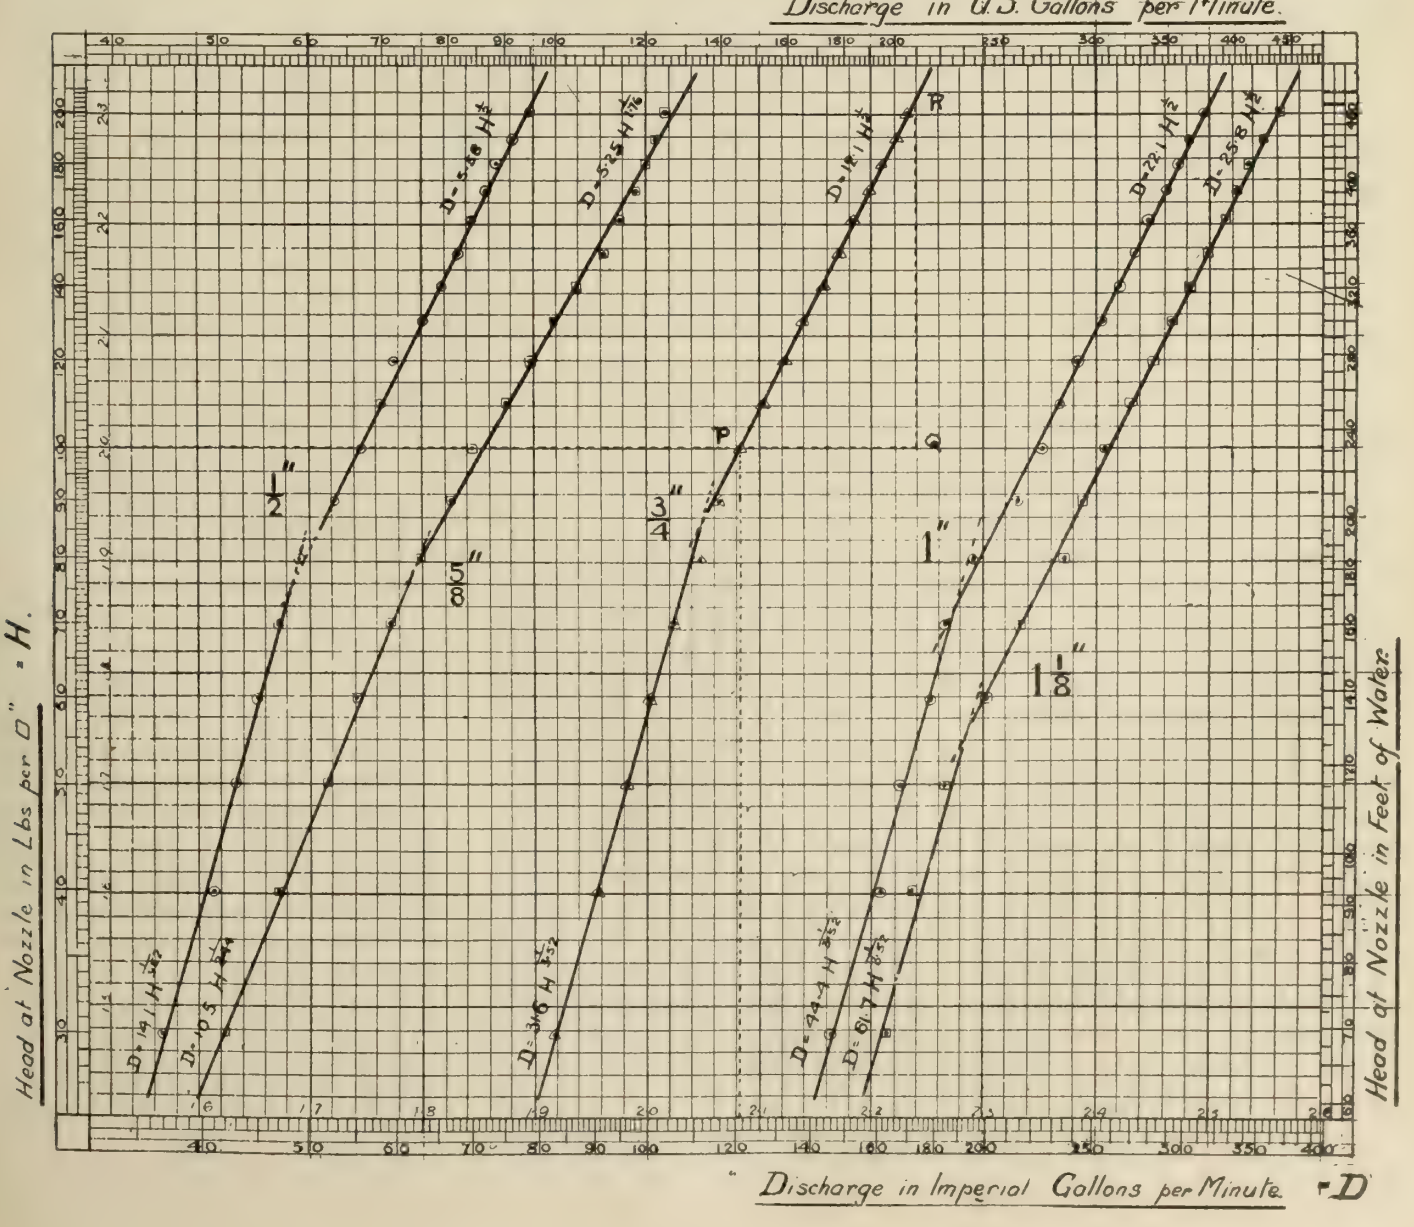
*Designers with the John Inglis Co. Toronto.

Similarly, if we take 1 lb. per sq. inch to be equivalent to a head of 2.31 feet of water, the 'feet' scale is obtained by lowering the lbs. per sq. inch scale through a distance=log 2.31 (i.e. 0.367) on the scale of logarithms.

Apparatus and Experiment.

The arrangement of the apparatus and the type of nozzle are shown in drawing. The nozzles were arranged in order of size in a row upon a 10 in. diam. horizontal pipe; the largest nozzle was towards the supply end, and an air vessel was provided at the closed end. Each nozzle was isolated by a gate valve with a clear bore of area not less than five times that of the nozzle, and the length of the parrallel bore at the outlet of each nozzle was at least equal to the diameter of the nozzle.

The water was delivered to the 10 in. main by means of a plunger pump, and was measured by counting the revolutions of the pump; a correction being made for slip at each pressure. The slip was measured by shutting down the discharge valve and driving the pump to keep the required pressure constant. For example, if the pump was driven at 50 r.p.m. to maintain a pressure of 100 pds. per sq. inch during an experiment, and if, when the discharge valve was closed the pump had to make one r.p.m. to keep the pressure at 100 pds. per sq. inch, then the slip was taken as 1 in 50 or 2 per cent. Precautions were taken to have fairly steady conditions before taking any readings.



Conclusions.

All the nozzles were 'ringed,' i.e., they had an inside shoulder as shown in drawing, except the $\frac{5}{8}$ inch nozzle which was made from the $\frac{1}{2}$ inch pattern by boring away the ring, and which was therefore a smooth nozzle. This probably accounts for the fact of the discharge being relatively greater in the case of this nozzle, as the restriction of the flow would be less than in the others. The diagram shows this greater discharge very clearly by the altered slope of the curve.

That all the points should lie so nearly upon straight lines, and that these lines should be parallel for similar nozzles, would indicate that the method of measuring the discharge, adopted in making the experiments, was a reliable one.

It is at once evident from the diagram that each curve consists of two distinct portions, indicating two laws of resistance to the flow of the water. Up to the bend in the curve the resistance follows a definite law, but at the bend a velocity is reached at which the resistance becomes less, and it continues to be less, according to a new definite law, throughout the higher velocities.

It is supposed that this change in the law of resistance was due to the proximity of the gate valve to the orifice. The gate valve was equivalent to a sudden enlargement in the area of the pipe section and this would cause additional eddies and increase the resistance to the

flow at the lower velocities. It is however conceivable that a certain velocity would be reached at which the water would shoot past the valve so quickly that it would not be sensibly affected by the enlargement; the latter would cease to produce a noticeable increase in the resistance, and this would obtain for all higher velocities.

It is therefore concluded that the results given in the table and diagram admit of practical application only under circumstances where the conditions of experiment are approximately obtained with regard to the position of the nozzle with reference to the gate valve.

The object of the above experiments was the calibration of an apparatus for the testing of centrifugal pumps.

A Day's Ramble Through the M.C.R. Shops at St. Thomas

By Fred. H. Moody

Every Shop has its Ways and Means of Meeting Exigiencies That Arise in the Shape of Unusual or New Jobs, but the Railway Repair Shop has an Exceptionally Large Number of Such Special Tools. The M. C. R. Shops, Under the Direction of an able Staff of Men, have Developed Numerous Special Methods and Devices, a Number of Which Were Picked up by the Writer in a Recent Trip Through the Shops, and are Here Given with Some Detail, as They Will Doubtless Prove Beneficial to Machinists, in General, in Developing Initiative for Undertaking New Jobs.

PART II.

Boiler Shop.

Coming to the boiler shop, a number of special tools are to be found, a few of which will be described. Fig. 10 shows a holding-on tool that has several unique features. It will be noticed that it can be used close in against any side sheet by using the outer holding-on bar. The device consists of a piece of heavy wrought iron pipe A bored as shown. There are two covers BB screwed on, the top one having openings. Inside is the piston C built up as indicated, with a leather packing ring. From this piston, extend two rods, D and E, of which D is centrally located, and E, offset. Normally D is used, but where the rivets are up close to a side, as for example the rivets between the boiler shell and head, the die on E is made use of. Air is introduced by the usual air valve and hose, below the piston C, forcing the desired die against the rivet head. As will be noticed, the dies on the heads of D and E may be replaced with others to suit the rivet in hand.

Another holding on tool is shown in Fig. 11, and is one that is only employed where the clearance space above the rivet is small, as in the water leg, where the working space is never over 4 or 5 inches. The usual method of doing this work is by a cup and wedge bar, a rather inconvenient method. The holding on block under discussion, is loosely suspended in the water leg by a wire through hole A. The hot rivet is placed in its hole, and the bevelled edge B placed against its head. A drift pin is then shoved through a stay bolt hole from the firebox, and engages with either one of holes CC. Pressure from the firebox on the drift pin, holds this bevelled face B tight over the rivet, which can be riveted from the outside of the boiler. While apparently a rather unstable arrangement, the results from its use are excellent, and besides, it is much more convenient than the before mentioned customary method of cup and wedge bar.

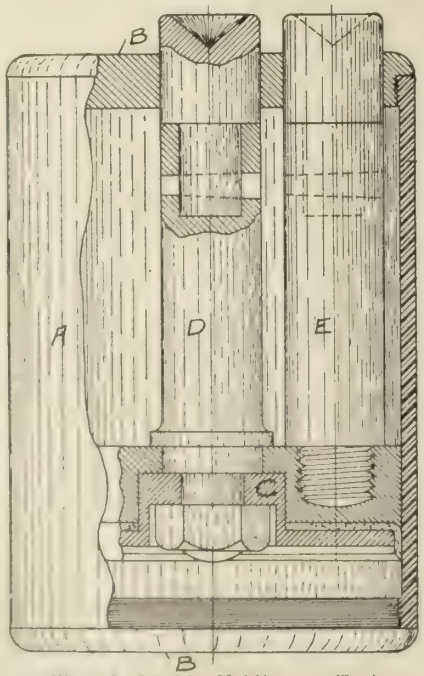

Fig. 10—Double Holding-on Tool.

The stay bolt socket, Fig. 12, is unique in that it is equally good for driving in, or removing stay bolts. As can be seen, it consists of a tool steel engaging piece A in a soft steel shell B to fit an air drill. The two are keyed at C. The engaging piece A has tapered flutes like an external reamer, only the halves are symmetrically the same, one half being effective in screwing in the stay-bolts, and the other half in the removing operation. The taper makes the grip very positive. When A is worn out, the part B is still useful for a new grip.

Continuing on the subject of stay-bolts there are several original ideas in use at these shops. For example, a new type of stay bolt tap is extensively used. It is believed, and justly too, that the usual stay bolt tap, reams the hole much

larger than it should be before the tap takes a grip and a thread begun. The tap used here is short, and straight up to within an inch and a half, or so, from the end, when. instead of being ground

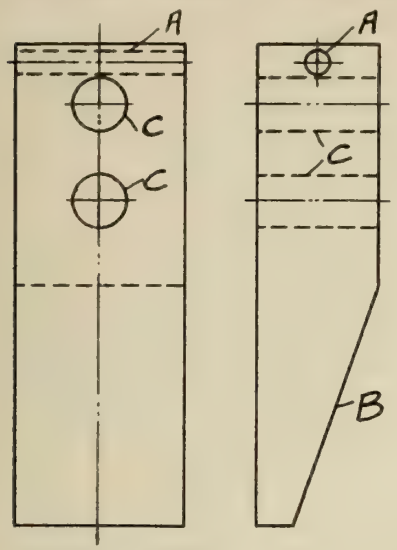

Fig. 11—Holding-on Block.

down the thread is cut on the taper. Thus, there is always a full thread, the tips being, of course, smaller in diameter. The full thread always grips without slipping, and reaming the hole. While more expensive, the extra cost is warranted by the superiority of the work.

Carrying out this same principle, they have a good way of tapping for radial stay-bolts. A hollow tap of the form just mentioned, is slipped over the reduced end of a round bar, the latter slightly smaller than the punched holes. This act as a guide for the tapping operation through the outer sheet, when a similar operation is performed from the inside, through the inner sheet, the rod guiding in the inner and outer sheets in each operation, respectively.

Blacksmith Shop.

Fig. 13 shows an anvil used in the smith shop for forging tapers on rods or bars. It is essentially the usual steam hammer anvil, with an inserted circular piece A. This piece can be moved around to make its upper face at any angle with the face of the stationary part. Bevels can thereby be forged very expeditiously. The arrangement is so simple, further explanation is unnecessary.

The springs under the locomotive, are built up of a number of strips of spring steel of varying length, with a collar around the whole to band them together. Fig. 14 shows a press employed in this banding operation. It consists of an old air compressor cylinder A, and a forging B. On the end of the air piston rod is a head C. The pile of component parts of the spring are placed on this head, located centrally. Air pressure in A lifts the pile against the projecting arm of B, compressing them together snugly. A clamp is then placed over this com-

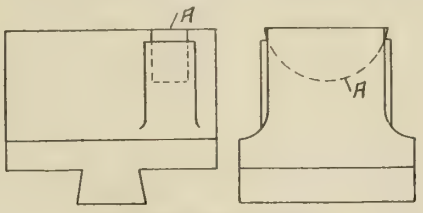

Fig. 13—Taper Anvil.

pressed bundle just off centre. The pressure is then relieved, and the spring removed. The clamp being to one side leaves the centre free to have the retaining band shrunk on. The usual method of banding, is to put a large collar over the bundle, and compress by driving a wedge in between the large collar and

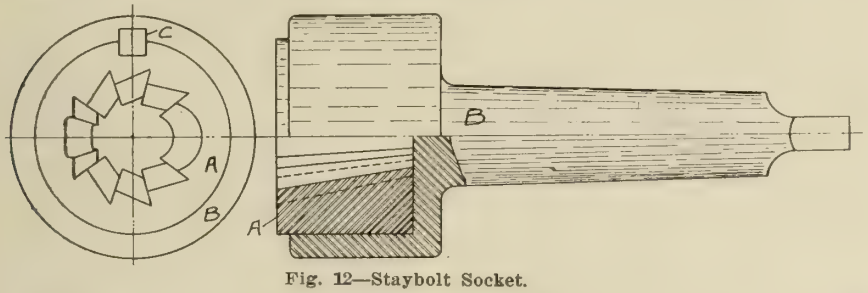

Fig. 12—Staybolt Socket.

the springs, after which the retaining band is shrunk on. The method described is much more expeditious, and allows of no error in adjustment.

A large variety of work is handled in the car repair department, giving a wide range of appliances. The most interesting operations are those on the bulldozer, where a number of special dies have been prepared. Such parts as the car sill, step and coupler pocket, are made in a very simple manner, the former in one operation, and the latter in three.

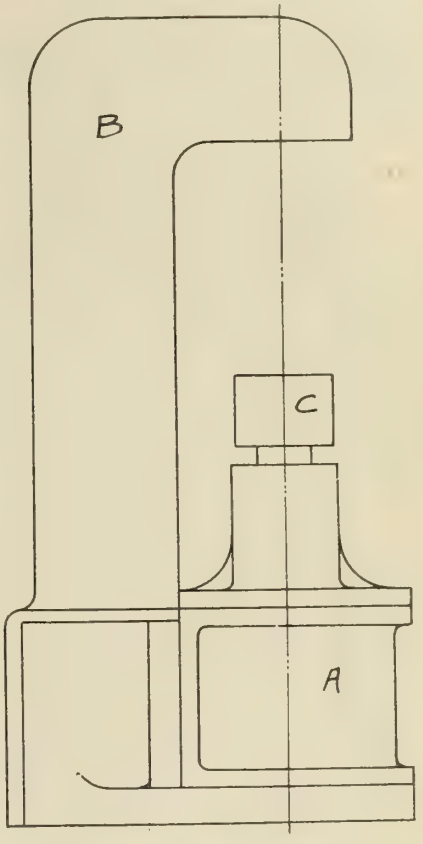

Fig. 14—Spring Press.

Fig. 15 shows a neat bending device for making eye bolts. The piece to be bent is placed against the angle A and clamped there by eccentric B. The roller C on arm D, which has previously been swung around behind the bar to be bent, is swung around in the opposite direction, bending the bar around the centre pin E. The distance between pin E and roller C is the thickness of the stock to be bent. This distance can be

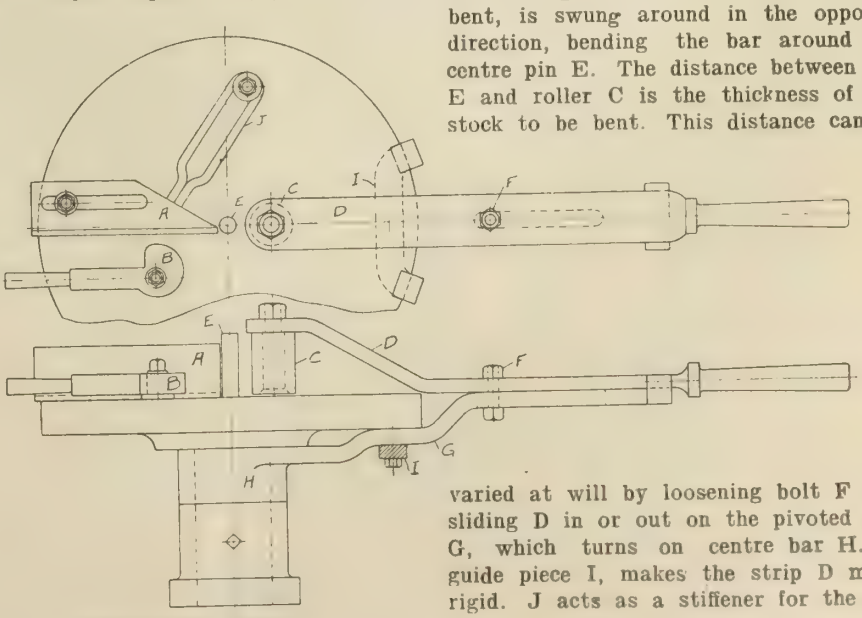

Fig. 15—Eye Bender.

varied at will by loosening bolt F and sliding D in or out on the pivoted bar G, which turns on centre bar H. A guide piece I, makes the strip D more rigid. J acts as a stiffener for the an-

gle A which can be adjusted to suit the work, as it is slotted as shown.

The punch press in the car shop has

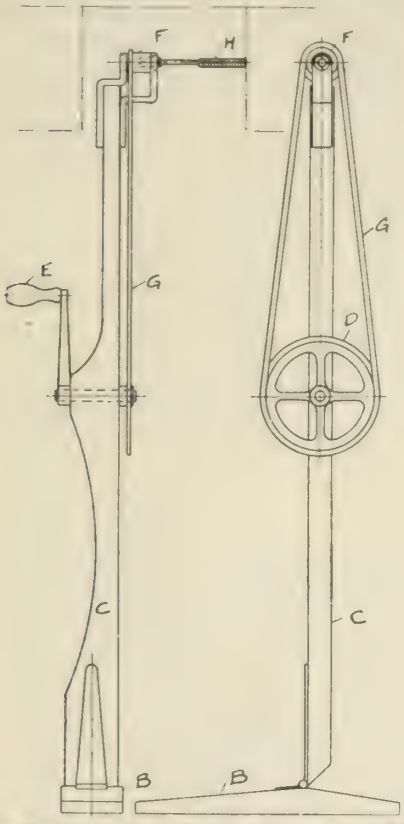

Fig. 16—Wood Drill for use between Car Sills

a spacer for spacing rivet holes in plates or bars. The spacer consists of a long piece of metal with a groove, through which bolts are secured. The upper end of the bolt is so made as to fit the size of hole being punched. Being adjustable, it can be set to engage with a punched hole the proper distance from the hole to be punched, thereby properly spacing the holes.

Fig. 16 shows a home-made drill for drilling in the confined space between the sills of cars. AA are car sills, in which holes are to be drilled. The device consists of a wooden base B to which an upright wooden arm C is hinged. On C is an old bicycle sprocket D with handle E. D drives a smaller sprocket F through chain G. Sprocket F has a square recess to hold the wood bit H. The method of operating is self-explanatory.

In the car shop, repairs were being made to the cement floor, which had holes in places. A composition of cement and cast iron chips, a mixture frequently employed, was being used, the results proving very satisfactory, the mixture forming a hard, wear-resisting surface.

Round House.

For removing the locomotive drivers, sections of the rail over the pit must be removable to allow of the wheel dropping. The arched rail used by the M. C.R. is shown in Fig. 17. The customary method of bracing this removable section, is to put a heavy casting under the rail, making the removable section very unwieldly. The method shown makes for a lighter construction.

The jack for lowering the locomotive drivers, is also shown in Fig. 17. It is of the telescope construction, allowing of a more compact arrangement, much shallower than the straight lift type would permit. The sleeves slide past each other, the whole being actuated by compressed air. The jack is on a small truck, which moves lengthwise on a larger truck, the latter having a track long enough to run outside and clear the locomotive rails. This is to permit of lifting the drivers completely away from the locomotive for repairs. The whole construction is clearly shown by the cut.

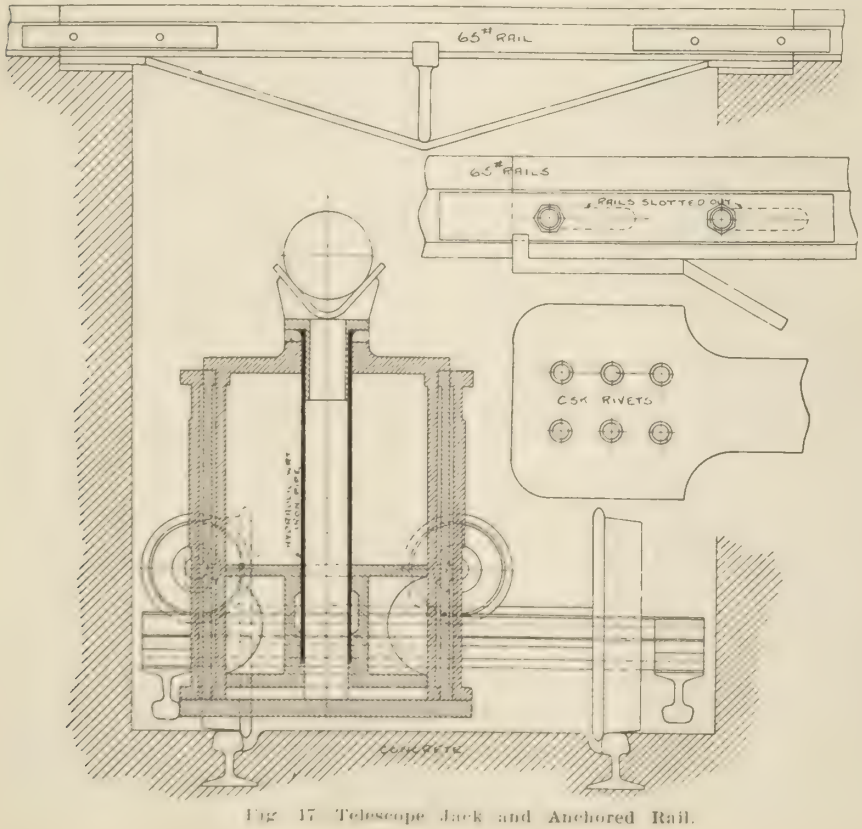

Fig. 17 Telescope Jack and Anchored Rail.

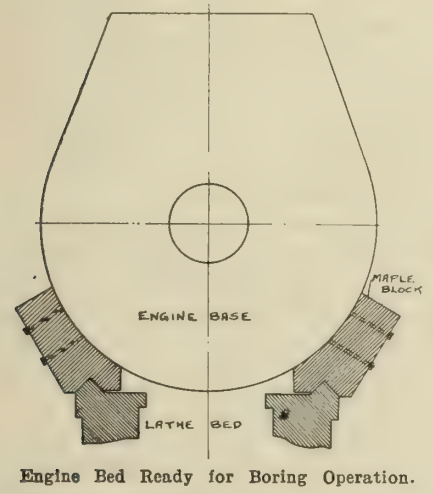
COBALT-CHROMIUM ALLOY.

Stellite is the name of a Cobalt chromium alloy which has been discovered by Elwood Haynes. It can be made into cutting tools which meet all the requirements of ordinary use and will not tarnish or rust. The inventor has tested the new alloy in many forms, having used it in razor blades and in lathe tools for cutting steel at a high rate of speed. The razor blades, although taking a satisfactory edge, were acknowledged inferior to steel razors on account of requiring more frequent stropping, but for many tools the alloy was found superior to steel.

Notwithstanding the great hardness of the alloy, it not only forges readily at a red heat, but can be bent at a right angle cold, either in the form of a cast or forged bar, provided the dimensions do not exceed one-fourth inch square. Its elastic limit is not quite equal to that of tool steel of the same hardness, but it is much tougher. In color the metal stands between silver and steel, and if suitably polished shows a high lustre. Many experiments were made before an alloy could be produced that would forge out perfectly into thin strips, and shows no tendency to check. After cooling, these strips are as hard as mild-tempered steel, and can scarcely be scratched by a file. A kitchen knife blade was made from this material, and after two years of use showed not the faintest sign of tarnishing. If held in the sun it produced a reflection that would dazzle the eye.

A lathe tool test was made against high speed steel, and it was found that the stellite tool would cut a continuous shaving from the bar at the speed of two hundred feet per minute, while the high speed alloy steel tools failed almost instantly. It does not follow from this that the alloy is better suited for high speed lathe tools than good alloy steel, but simply that it will stand a higher speed without softening. It would not be reasonable to expect a revolution in tool-making on account of this discovery. There is in the new alloy a possible outlet for the great Cobalt production of Ontario's silver mines. This gives the matter special interest in Ontario at the present time.

MACHINE SHOP METHODS AND DEVICES



Unique Ways of Doing Things in the Machine Shop. Readers' Opinions Concerning Shop Practice. Data for Machinists. Contributions paid for.

LARGE JOB IN SMALL SHOP.

By Frank E. Booth.

The job in question was the boring out of the five bearing boxes of a four cylinder vertical internal combustion engine.

The only machine available for the job was a Bertram lathe having 16 inches swing between the centre and the ways, with a distance of 8 ft. between centres. The engine base was about 6 ft. 6 in. long,

Engine Bed Ready for Boring Operation.

while the longest bearing was 8 inches.

The job was bolted firmly to the lathe carriage at one end, while the other end was supported by two hardwood blocks bolted to the engine base, and fitted to the lathe ways as shown in the sketch. A solid boring bar, with a head for carrying the tool, was used, and the head was shifted from one box to the other as the job progressed. A first class job was the result.

CRANK SHAFT JIG.

In the shops of the Canada Gas Power and Producer Co., Barrie, Ont., there is a very convenient form of jig in use for turning the crank pin of the solid crank shafts used in the Weber engines built by that concern. This method of machining is due to E. J. Graves, superintendent of the plant.

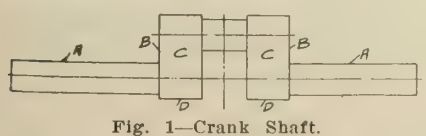


Fig. 1—Crank Shaft.

The chuck or face plate of the lathe is removed, and the jig which is threaded at A to correspond to the lathe spindle, is screwed on. Either end A of the crank shaft is then inserted into hole B of the jig, so that the face B of the shaft is flush with face C of the jig. The offset C of the crank sets into recess D of the jig, and set screws E can be adjusted to centralize the crank pin. The clamping screws F are then

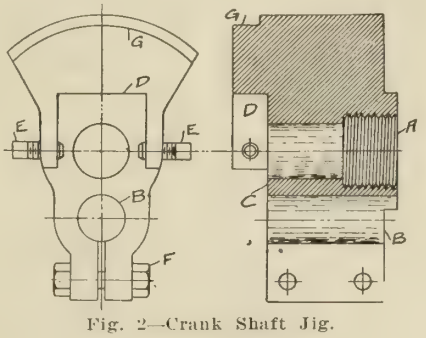

Fig. 2—Crank Shaft Jig.

tightened and the crank pin is ready to turn.

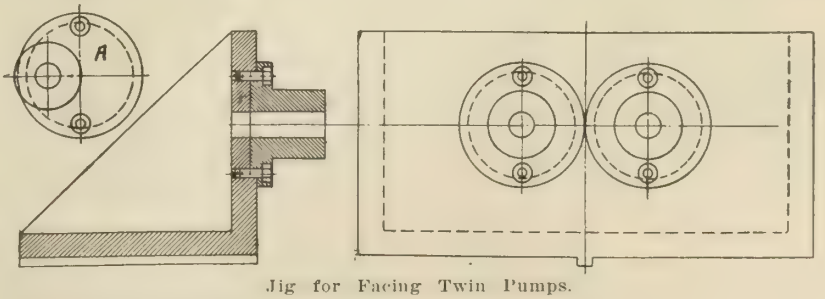
Of course, different sizes of jigs are required for the various kinds of shafts produced. Each jig has another feature of interest. The radius of the contour G of the jig is made the proper radius of the edge D of the crank shaft, from the crank pin centre, so that the tool is quickly set to reduce the shaft to the proper size.

CUTTING LONG LEAD SCREW.

Cutting a 41 ft. lead screw in a shop where the longest lathe is 22 ft. presents a problem. But this was recently overcome in the works of the John Bertram & Sons Co., Dundas. A still more difficult act was the cutting of a 45 ft. lead screw, more than double the length of the lathe on this same lathe.

The first lead screw referred to is, to be exact, 40 ft. 10¼ ins. long, 2 in. pitch, double thread and 4⅛ in. diameter. The screw was mounted in the lathe with outward bearings set up for the overhang. The thread was cut half way along the leadscrew, reversed, and the other half cut.

In cutting the 45 ft. lead screw, it was made in three equal parts. The centre piece had the screw cut on it, leaving a short piece not cut at each end. The two other parts were then welded on, one on each end. The screw was then mounted and a procedure similar to that already described followed.



In connection with cutting lead screws, the John Bertram & Sons Co. keep master lead screws, absolutely accurate, and periodically lead screws on the lathes in the shop are renewed to conform with the master lead screw. In this way accurate lathe work in the production of machine tools is assured. It is of interest that the lathe with a 22-ft. bed mentioned above, was built by the John Bertram & Sons Co. and was used by Henry Bertram, the present general manager, to cut lead screws in 1875.

JIG FOR FACING TWIN PUMPS.

One of the principal products of the Canada Foundry Co., is feed pumps for varied uses. To facilitate rapid production, many useful devices in the form of jigs, special machines, etc., are employed. One of the most interesting of these jigs, is the one shown in the accompanying sketch, which is used for machining the valve face, motion bracket, and body of the steam cylinder and stretcher, all at one setting.

The device consists essentially of two cast iron angle plates, to which are attached removable collars. The bore of the cylinder just fits over the collar at one end, and the collars on the other angle plate, fit into the ends of the cylinder stretchers.

As shown the jig will only apply to one spacing of cylinders, that is, for a given distance apart of centres, but, by the use of eccentric collars as shown at A, any distance apart may be handled by the use of the proper collars. As the company uses it, the jig is made for 5 inch centres, with eccentrics for 7½ inch centres.

Jig for Facing Twin Pumps.

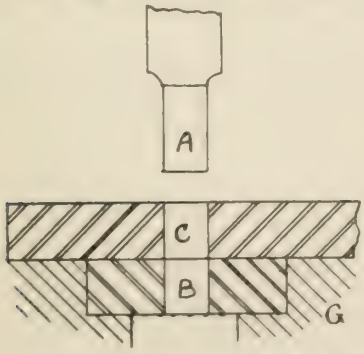
HIGH SPEED CUTTER.

John Bertram & Sons Co., Dundas, cut a large number of steel gears from the solid. In machining them and cutting the gear teeth great difficulty was encountered in securing cutters to stand up to the work. After some experimenting, however, a cutter was designed with each tooth tapered from the nose towards the centre of the cutter. With such a cutter a speed of 120 ft. per min. is maintained and 50 per cent. of the time is saved. This is attributed to the relieving of the teeth on the sides.

PITCH OF PROPELLER.

In the November issue of Canadian Machinery, R. Ewart Cleaton gave an article on "Practical Method of Obtaining Pitch of Propeller." We find, however, that the printers have made a serious error in Simpson's Rule which should read as follows:—

$$a = \frac{y}{3}(E + 4S + 2m)$$



Where a = Area in square inches.
y = Distance between ordinates.
E = Sum of extreme ordinates.
S = Sum of even ordinates.
m = Sum of odd ordinates.

ECONOMIC PUNCHING.

By K. Campbell.

There were a great many bars to be machined in the plant where I served my apprenticeship. These were about 2½ in. by ½ in., and had from 15 to 20 holes drilled in each. This cost 6 or 8 cents each, and they were then countersunk at a cost of 2 or 3 cents each additional. High speed steels were then introduced, making the cost less than this, yet allowing the drill operator to make a slightly larger amount per day.

It was then found that more of these were needed, and unless some means were devised, additional drills would have to be installed. It was finally decided to punch them, and the bars were then punched one hole at a time. This put the idea into the management of punching all the holes at once. As there was other work that could be done economically on a big punch, it was decided to instal one. This was done, and all the holes were punched at once. In Fig. 1, A is the punch, C the work, and B the die, G representing the machine frame.

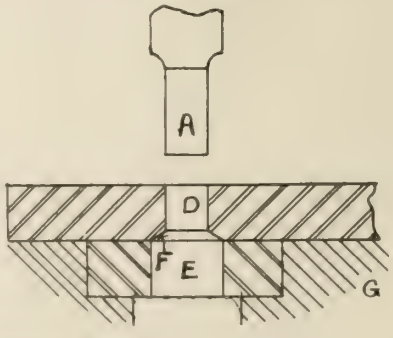


Fig. 1.—Economic Punching. Fig. 2.

The bars were finished much more quickly, but they still required to be taken to the drills to be countersunk until the method shown in Fig. was adopted. A is the punch, B is the work when completed, F shows the countersunk bar, E the hardened die, and G representing the punch frame. It will be noted that the die is the diameter of the countersink. In this way the second handling of the bars was done away with, and the work done very cheaply.

Another job that was done on this large multiple punch was the work on binder bottoms. Formerly these were done on a single punch. The steel bottoms were fastened to the template with steel bushings, the whole being on a large table with handles at each end. Two men operated the table and one the punch. The job was one of the most hated in the shop, and there was rejoicing when dies were made for the multiple punch to allow it being done on that machine. It made a big saving for the company, but incidentally it eliminated the days of hard, heavy lifting of the table, bottom and template, which had to be done for each hole punched, there being 50 or 60 in each binder bottom. These holes were of three different sizes which necessitated handling them three times.

TOGGLE JOINT ACTION.

The toggle joint is used on various machines, such as rock crushers, presses for stamping sheet metal, etc. The two accompanying line drawings show the application of the toggle joint to a press. Referring to these, A is a crank keyed to the main crank-shaft of the press. Connecting-rod E, attached to this, is pivoted in yoke H, which is suspended on rocker arms F and G, pivoted to the side frames of the machine, on opposite sides of H. Bell crank levers D are operated from the center pivot of H, through short links J. Links C connect the upper arms of bell cranks D with cranks B, which are keyed to rocker arm shafts.

A comparison of the two illustrations will show the action of the mechanism. In Fig. 1, crank A is at its highest position. In Fig. 2, the blank holder is down. It will be seen that in this position bell cranks D and links C are straightened out, so that a powerful

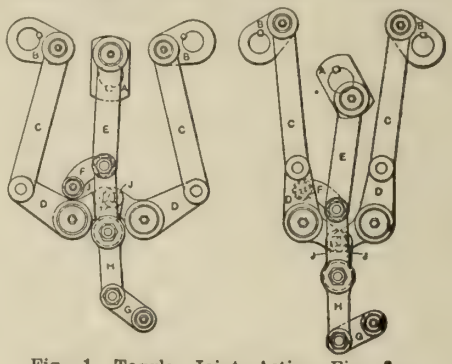

Fig. 1.—Toggle Joint Action—Fig. 2.—

toggle action with an appropriate dwell is obtained, lasting through a considerable portion of the revolution of the crank-shaft.

Cranks B, in turn, operate the rocker arms, which, with the links connecting them with the blank holder slide form a second toggle joint mechanism. It will be seen that these two sets or toggle joints, acting in series as they do, give a powerful pressure to the blank holder, estimated at 2,000 tons.

SAVING SHEET METAL.

In stamping sheet metal, it is possible to waste a lot of metal. Fig. 1 shows a method of stamping out washers where there is a large amount of waste. It will be evident from Fig. 2 that by stag-

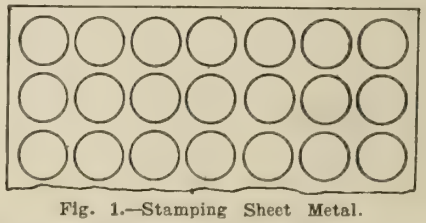

Fig. 1.—Stamping Sheet Metal.

gering the rows or cutting them zig-zag, more washers can be cut out of a sheet of metal. The E. W. Bliss Co., manu-

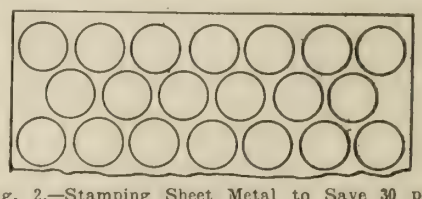

Fig. 2.—Stamping Sheet Metal to Save 30 per Cent.

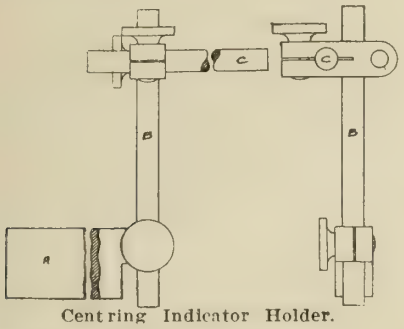
facturers of presses, have estimated this saving at from 5 to 30 per cent.



By making the cuts touch each other as much as possible, it is possible to secure the maximum economy in stamping out washers. In order that the centre of

the washer be not wasted, these can be used for making smaller washers.

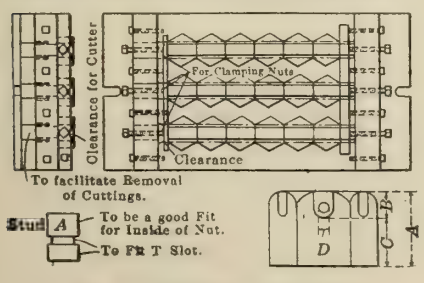
CENTRING INDICATOR HOLDER.

This is a simple little device used in the tool-room of the London Machine Tool Co., Hamilton, for carrying the Starret Indicator No. 64. It was designed by the foreman toolmaker with the object of greater flexibility in getting at unhandy centres, as by this device, the connecting arms make any position of the indicator practically possible.

A is held in the tool post of the

Centring Indicator Holder.

lathe, while the indicator is attached to arm C, the intervening arm B being used to increase the range. A is a piece of machinery steel, and rods B and C are of stub steel, requiring no extra finish. The joint between B and C is cast steel, slit at the ends to facilitate clamping, making in all a very simple and useful device. Tool-makers and machinists will find this a useful addition to their outfits, and it requires very little time or exertion to make.



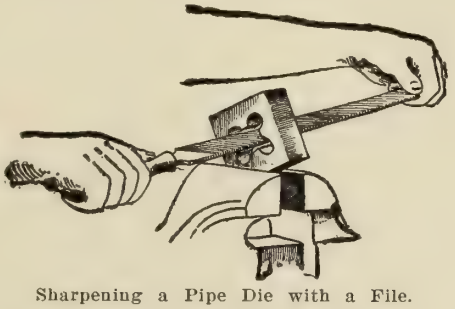
JIG FOR HOLDING CASTLE NUTS WHILE CUTTING SLOTS.

By G. C. White.

In the works of the C.P.R. at Montreal, a jig similar to the one shown in the cut is used for holding nuts so that

Diameter of Bolt	A	B	C	D	Width across Flats *
⅜"	1¼"	5/16"	11/16"	¼"	1 7/16"
½"	1¼"	5/16"	1 3/16"	¼"	1 5/8"
1¼"	1⅜"	½"	⅞"	5/16"	1 11/16"
1¼"	1½"	½"	1"	5/16"	2"
1⅜"	1⅝"	½"	1⅛"	5/16"	2 1/16"
1½"	1¾"	½"	1¼"	5/16"	2⅜"

* These are the only Dimension for the Unfinished Nut.



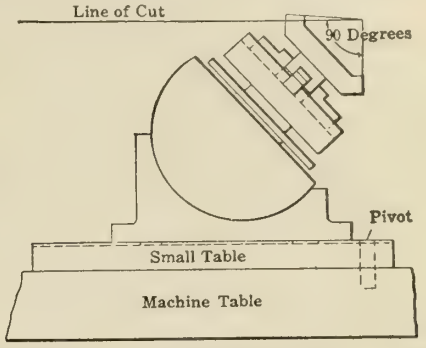
Jig for Slotting Castle Nuts.

they may have slots cut in them. The machine used is an old universal milling machine, which is operated by an apprentice. The only difficulty, if it may be termed such, is that for every size of nut there must be a different-sized stud. This jig enables the company to turn out approximately, thirty ⅞-inch, twenty-six 1-inch, twenty-four 1⅛-inch, twenty-two 1¼-inch, eighteen 1⅜-inch or eighteen 1½-inch nuts every 45 minutes.—American Machinist.

TO SHARPEN A PIPE DIE.

By A. F. Bishop.

I discovered a short time ago that a mill-cut file would sharpen a solid pipe die quite easily and quickly without removing the temper in the die. The first few rubs of the file will slide without



Sharpening a Pipe Die with a File.

cutting, this being due to the grease on the die. Just as soon as the greasy surface is thoroughly worked off, the file will commence to cut, and will cut very smoothly, making a keen edge on the cutting thread. Heretofore I have always worked on emery grinders to try to do this work without removing the temper of the die, but found they worked very slowly on account of the small diameter of the wheels, also that it was quite a nuisance to set the die for the cutting wheel. Most mechanics would not try the file, not having the least idea that it would do the work. That was my case.—Scientific American.

FIXTURE FOR CUTTING MITRE GEARS.

The following method for cutting the teeth in mitre-gear blanks, on a No. 2 plain milling machine with a universal head, is given in the American Machinist. The gears are mild steel, 37 teeth, 6 pitch. They are finished in two cuts and do not require filing. They wear well and run quietly.

A small table with a groove up the centre for the head is secured to the machine table, a ⅝-inch pin being in one end acting as a pivot about which the small table is free to swing. After the blank is set this table is strapped securely. The face and cut angles of a mitre gear together make 90 degrees, and it follows that when the blank is set up for cutting, the apex of the cone angle is in a vertical line with the face of the blank. The blank is set so that this vertical line falls in the centre of the ⅝-inch pin. The table with head is

Fixture for Cutting Mitre Gears on a Plain Milling Machine.

now swung either way an amount that will give a correctly shaped tooth on that side. After going around, swing the table the same amount in the other direction. Of course, the cutter must be set in position before the table is swung either way. The amount to set the table over will have to be found by trial, but once found the same marks will answer for any size mitre gear. The sketch shows this arrangement.

COMBINED DRILLING AND MILLING JIG.

By Wilfrid J. Thompson.

The inclosed sketch is of a jig used for both drilling and milling the lugs of a small eccentric strap, shown at F. A, Fig. 1, is gray iron with the plate B (the drill guide) screwed and doweled to it. C is the locating stop, which is of hardened steel and fits fairly well in the rough ⅝-inch groove in the strap.

The block D is of machinery steel about 1¼ inches wide and is forced up by the wedge E against the bottom of

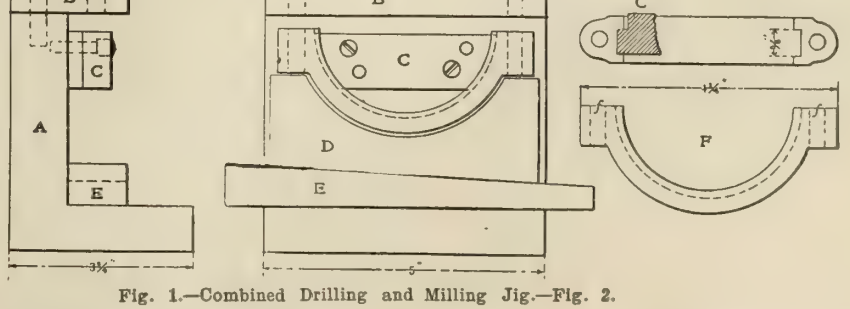


Fig. 1.—Combined Drilling and Milling Jig.—Fig. 2.

the lugs of the strap locating the latter with C and parallel with the top of the jig.

Fig. 2 shows the work in position ready to be drilled. When used as a milling fixture the plate B is first removed. Fig. 1 shows an end view of the jig without the work or block D in place. C_1 is a part section of C.

This is a cheap, easy jig to make, quick to operate, and about as near toolproof as any tool can be.—American Machinist.

INFLUENCE OF GALVANIZING ON STRENGTH OF WIRE.

Wire woven into ropes and cables and used for the most part where the weather exerts a deteriorating influence, requires suitable protection, if its usefulness is to be a dependable factor. Coating with zinc has been found to answer the purpose admirably. Experiment and investigation show the formation of a couplet, in which the zinc of the galvanized iron forms the electro positive element, and the iron the electro-negative, when the material is immersed in water or other fluid. The zinc takes up oxygen, gradually forming a zinc oxide, while on account of the evolution of hydrogen, the iron remains inert, even if the continuity of the zinc coating is slightly broken.

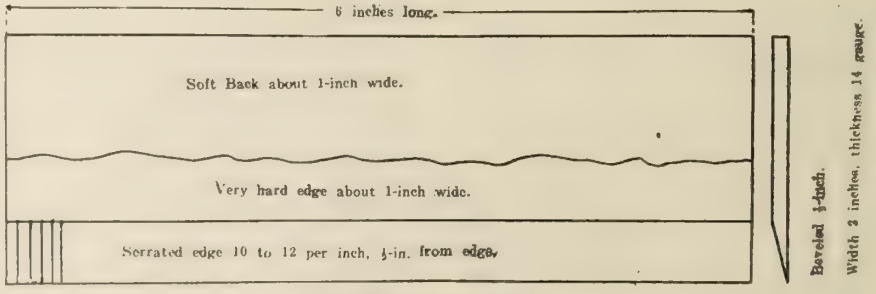
In the process of hot galvanizing, there is no question but that the strength and particularly the resistance to bending and torsion, are considerably affected. Many theories have been propounded to explain the loss of feusile strength. Poor material is cited, but the best has been shown to suffer. The "overdrawing" of the steel has been suggested, but microscopic tests under this head, fail to reveal it as a cause. Irregularity of zinc coating has also been suggested, but it likewise fails to reveal the situation.

Absorbed Hydrogen Gas Does the Damage

The results of many recent investigations show an absorption of hydrogen from the acid bath, in the pickling process previous to galvanizing, resulting in considerable damage to the finished products in the matter of brittleness. Further investigation showed, however, that heating the steel up to 250 degrees Fah. for four hours, removes this bad effect entirely, and shows that galvanized wire can be produced with a minimum loss of physical properties, it being entirely a question of proper practice in regard to removal of damage done by pickling, proper bath temperature, and time of wire remaining in it. The wire should be treated before galvanizing to remove the hydrogen, and the temperature of the zinc bath should be regulated between close limits. The latter is in nowise easy, these being difficulties in pyrometry and proper firing, where many wires are passed through constantly, with consequent irregular lowering of the temperature.

Correspondence

Comments on articles appearing in Canadian Machinery will be cheerfully welcomed and letters containing useful ideas will be paid for.



Information regarding manufacturers of various lines, with their addresses will be supplied either through these columns or by letter, on request. Address letters to Canadian Machinery, 143-149 University Ave., Toronto.—Editor.

Designing Propellers.

I have been much interested in reading the recent articles on propellers, their design, measuring of pitch, etc. When Mr. Baldwin set out to select an aviation propeller, he tried to select one from a number of various pitches. He tried to do this with a stationary outfit but found this method unsatisfactory, as the one making the best fan and turning out the greatest volume of air was of course not the best propeller. The selection for his airship was made by fitting up an ice-boat, the propeller selected making about sixty miles an hour.—Reader.

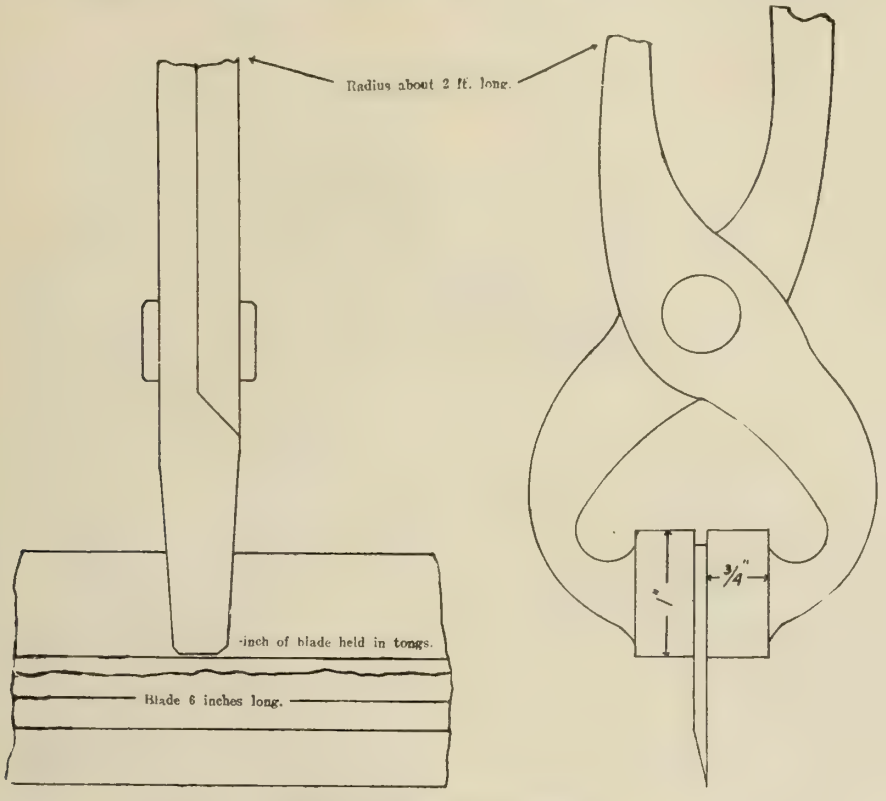
Tempering Small Shear Blades.

We are enclosing you sketch of a knife made of crucible or section steel. Dimensions are, length 6", width 2", and

Small Shear Blade.

14 G. thick, and to have soft back about 1" wide and cutting edge to have extreme hardness about 1" from edge and serrated about ½" from edge, 10 to 12 serrations per inch.

We have experienced much trouble from them warping while being dipped in the cooling bath. The substance we used for that purpose was spring and rain water, salt and water and fish oil, same as that used by the tanners and sometimes called "Tanners' Oil," but warping is caused from using any of the above if heated sufficiently to get the required hardness. While they require to be very hard, yet they must have toughness as well, as they are subject to severe strain and are liable to breakage.



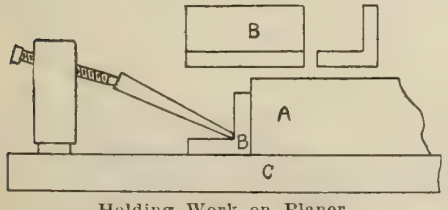
We would therefore consider it a favor if through the columns of "Canadian Machinery" you would prescribe method of heating and tempering the above knife.—C. Smith & Sons.

For heating, make up a large level topped fire on an ordinary blacksmith's hearth and on this lay a flat piece of ⅜" boiler plate, raise and maintain this plate at a bright cherry red heat—about 1480 degrees Fah.—lay the blades to be tempered on the plate until they attain the same heat, they should be then taken off carefully one at a time with a pair of narrow nosed flat tongs and dipped in a bath of rain water that has been raised to a temperature of 210 degrees Fah. "just off the boil," they should be quenched right out, "given all the water," as it is called, and afterwards polished with fine emery;—great care must be taken in dipping that the blades enter the bath exactly vertically and edge downwards. For letting down to the requisite degree of hardness, a pair of broad flat bitt tongs, as shown in the sketch, should be used, heat the tong bitts to a bright red and with them hold the blade to be treated about ¾" from its back edge, the heat of the tongs will draw the temper and when the right color shows on the cutting edge quench out in cold water again, taking care that the blade enters the water vertically. I should think that a medium straw color would represent about the right temper. It will be found that the whole temper will have been drawn from the back, leaving it normal and the hardness will graduate through to the edge, but to obtain a strictly defined line between hardness and softness would be practically impossible.

Any warping or buckling can be removed afterwards by hammering on a planed grey-iron block with a raw-hide mallet, first warming the blade slightly. This re-setting of thin hardened steel plates

is a special trade, known as saw smithing and experts can command very high wages.

In forging the blades great care should be taken against over heating—pure high carbon steel should be worked at as low a heat as possible, and for edge-tools should be always worked one way, "back to edge." If this is done and the steel be of good quality a uniform warping will be observed at the first dip; this can be rectified by bending the blade in the opposite direction before dipping, and it is quite possible to remove the article from the bath quite straight, this practice has to be followed in hardening some kinds of files.—Frank Walker.



Tongs for Tempering Blades.

These bunters can be made any shape to suit the work. For low work the bunter can be made with a low side and two or more can be used for a job. The bunters are made by milling the two surfaces next the planer bed and the work, a single cut being all that is necessary. They are made indestructible if made of good steel and hardened.—K. Campbell.

Holding Work on Planer.

In the December issue of Canadian Machinery a device was described for holding work on a planer. In the accompanying illustration is shown an angle plate B, sometimes called a bunter,

Holding Work on Planer.

holding the work A on the planer bed C. Its object is to prevent denting finished work which would ordinarily be held by toe dogs or fingers.

CISCOE LATHE TESTS.

An interesting test of a Ciscoe 14-in. lathe, made by the Cincinnati Iron & Steel Co., Cincinnati, Ohio, was made recently. Cuts were made in 0.25 per cent. carbon steel to a depth of 9-16 in. and 36 to the inch friction feed; in the same material to a depth of $\frac{3}{8}$ in. at 18 to the inch screw feed, and in cast iron to a depth of $\frac{7}{8}$ in. at 18 to the inch screw feed. In these tests it was endeavored to break the lathe, but the only part that broke was the belt. This is justly considered exceedingly heavy work for a 14-in. lathe and indicates very forcibly its powerful construction. For these lathes the company has recently has three orders from Canada, two from California, one from Texas and one from New York, and it has also received orders for considerable equipment, including larger lathes from Florida and miscellaneous small tools from Arkansas and Tennessee.

ADDITION TO EDITORIAL STAFF.

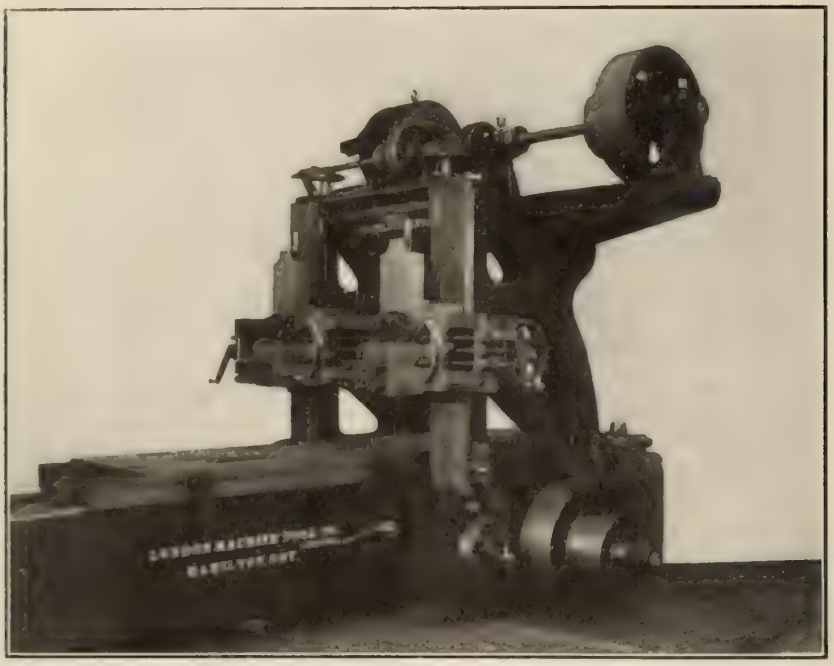
Since the first issue of Canadian Machinery it has been the aim of the publishers to keep in close touch with the developments in machinery, machine shop and engineering practice and thus give the readers accurate information on all subjects of interest to them. With the growth of the paper the work of keeping it up to the present high standard has necessitated an addition to its editorial staff. The publishers are pleased to announce that Peter Bain, M.E., formerly of Bain & Mitchell, Montreal, has joined the staff.

Mr. Bain has had 20 years experience in the mechanical engineering field. He is a Clyde technically and practically trained man, having served with Matthew, Paul & Co., manufacturers of stationary, marine and high speed engines. He was on the "Niobe," the cruiser recently bought by the Canadian Government, during her first trials after launching. He was assistant manager at Wm. Spence, Dublin, during the installation of the refrigeration, and mechanical apparatus in connection with the Guinness' brewery extension, and during the construction of a number of locomotives used in this large plant.

Since coming to Canada Mr. Bain served as chief draftsman with the John McDougall Caledonia Iron Works, Montreal, later forming a partnership with Mr. Mitchell, under the title of Bain & Mitchell. He designed the large modern power plant of the Montreal

PETER BAIN, M.E.,

Steel Works, and taught the classes in engineering at the Montreal Y.M.C.A., under the International Y.M.C.A. Educational Board. Many graduates of his classes now occupy important positions in the engineering field. Mr. Bain is therefore well qualified for editorial work on Canadian Machinery.



DEVELOPMENTS IN MACHINERY

New Machinery for Machine Shop, Foundry, Pattern Shop, Planing Mill; New Engines, Boilers, Electrical Machinery, Transmission Devices.

PLANER FOR HIGH SPEED STEEL.

The planer illustrated herewith is designed for the use of high speed steels. Convenience, accuracy and strength were the points considered in its design. For exceptional heavy work the planer may be equipped with double belt drive and pneumatic clutch.

The bed is made in deep box form of close grained iron. The sides are straight, neatly flanged on outside and inside at base. The cross braces are heavy, close together and the V's being well ribbed to web make a stiff and strong construction. The centre to centre of V's on planers is wide and the V's are also very wide. The bed is made sufficiently long to prevent table from lifting under the heaviest cuts when table is at extreme end of stroke.

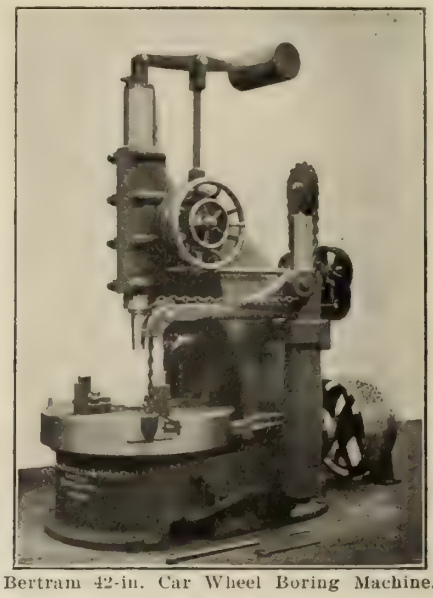
Planer, London Machine Tool Co., Hamilton.

The table is made deep and stiff, being well ribbed crosswise and lengthwise. The V's are so designed that to prevent grit or shaving from dropping through the table on to the sliding surface, where they will cut and score. The dirt will drop through the table, but will drop on the outside or inside of bed, where it can do no harm. The table is generally drilled with round holes. The T-slots on table are cut from the solid.

The rack is cut from the solid and is secured to planer by means of screws and dowels. The housings are made in heavy box form best calculated to resist the strain due to the heaviest cuts. The housings have a foot on floor, relieving the bed of any bending movement. The faces are scraped to cross bar, and are polished and frosted.

The cross bar has a long bearing on the housings, and is reinforced at centre by box of girder form cast solid with bar. The bar is raised and lowered by power on all sizes from 30 inch up.

The heads have down and angular feed. Slides are all scraped and are provided with gibs for taking up the wear, with means for locking. The gearing is all cut from the solid on accurate gear cutting machinery, and all pinions are of steel.



The feed rack is of steel cut from the solid steel bar, and the feed pinion is of steel. Ratchet pinions are all of steel.

This planer is manufactured by the London Machine Tool Co., Hamilton.

CAR WHEEL BORING MACHINE.

The illustration shows a car wheel boring machine made by the John Bertram Sons Co., Dundas. It has a capacity to bore wheels up to 42 ins. in diameter on the tread. It swings 48 ins. in diameter.

The table is provided with five self-centering gripping jaws. The cone has three steps 28, 24 and 20 ins. diameter for 6 in. belt. The boring spindle is counterbalanced and has quick return. It is also provided with three changes of feed, two for roughing and one for finishing, changes from roughing to finishing can be made instantly.

Bertram 42-in. Car Wheel Boring Machine.

The machine is complete with countershaft, wrenches, pneumatic air-hoisting attachment, and power hub facing attachment. By means of the lifting attachment the wheels are picked up from the floor without the aid of a jib, overhead or portable crane and deposited on the floor after machining. This is probably the first machine of this type regularly built.

POSITIVE CHAIN TONGS AND PIPE VISE.

The positive chain tongs shown in Fig. 1, present many features of interest and value to steamfitters and power plant engineers. They are made of drop forged steel, in sizes from ¾ to 12 inch

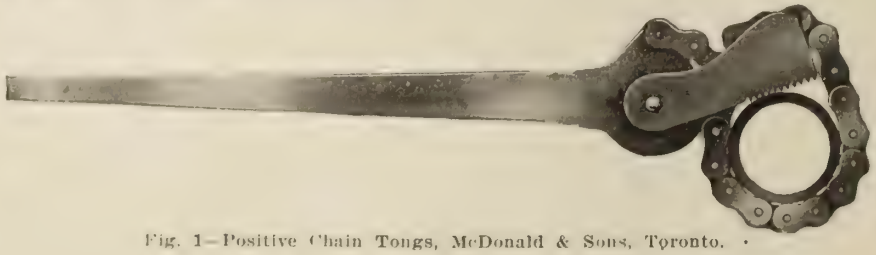


Fig. 1—Positive Chain Tongs, McDonald & Sons, Toronto.

pipe. They are simple in constructional details, strong, light and reliable, are equally useful as pipe or fittings tongs, and grip at all angles. The chain is strong, being made to stand strains in excess of any leverage that may be applied at the end of the handle.

Companion to the chain tongs is a pipe vise, illustrated in Figs. 2 and 3, the merits of which are as follows: It lies flat and open on the bench, permitting lengths of pipe to be placed in or withdrawn freely without risk of wear or damages to the jaws. There are four jaws instead of three as in most patterns, ensuring consequently better gripping qualities. The quick adjustment device consisting of loose nut with shank, knob and spring catch, enables pipe of varying sizes to be inserted and withdrawn without the labor attendant on turning the screw backward or forward each time.

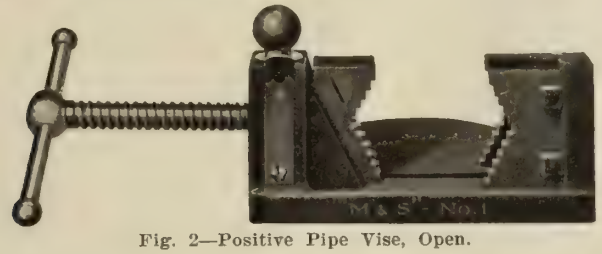

Fig. 2—Positive Pipe Vise, Open.

Fig. 3—Positive Pipe Vise, Closed.

The vise is neat and compact, is made in four sizes from ⅛ to 12 inch pipe, and is patented in Canada and the United States.

MacDonald and Sons, Toronto are the patentees and manufacturers of both specialties.

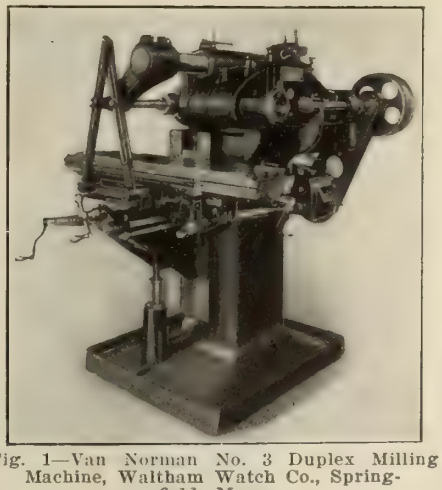
DUPLEX MILLING MACHINE.

The Waltham Watch Tool Co., Springfield, Mass., has placed on the market the No. 3 Van Norman duplex milling machine shown in Fig. 1. The special feature embodied in the construction of this machine that distinguishes it from other types of milling machines, is the movable cutter head, which is mounted on a ram or frame that may be adjusted in or out over the table to adapt the cutter for use in either a vertical or horizontal position, the cutter spindle being adjustable to any angle from the horizontal to the vertical. Among the features incorporated in the design of the No. 3 size which are not found in the sizes formerly built, may be mentioned the single pulley or constant speed drive with a change gear mechanism for varying the spindle speeds, located in the ram; a geared feeding mechanism; an improved box type of knee; and a solid steel overhanging arm, which braces to give rigidity for either vertical or horizontal cuts.

This machine is solidly constructed throughout and it has ample power for both spindle drive and feed mechanism. The details of the drive and the spindle change gear mechanism are seen in the sectional views, Figs. 2 and 3. The driving pulley A, Fig. 2, is mounted on a splined shaft a, which is supported in a bracket B, attached to the side of the machine column.

There are twelve changes of spindle speeds, varying from 15 to 276 r.p.m., the speed changes being effected by operating the sliding gears F and I and the clutch N. All the gears are of steel, and those within the ram run in an oil bath. A handwheel on the end of shaft f may be used to facilitate bringing the gears into mesh when making changes.

The cutter-head W, which has a 90 degree angular adjustment, pivots on the trunnion ring T. The head is securely clamped on the face of the ram by three locking bolts which move in circular T slots. A bevel gear U on the end of shaft f, and a bevel gear V on the spindle, complete the drive connection. The cutter spindle has the conical form of bearings, and is made with a No. 13 B. & S. taper, to adapt it for holding the large collet holder or reducing collets that are used in this machine. The ram may be securely clamped to the column by means of two binder levers, after the cutter spindle is located in the most advantageous position for operation. This ram has a 13-inch movement in and out over the column, and the adjustment is effected by means of the crank shown near the top of the column. The length of the ram is 35 inches and the width 11½ inches. The driving pulley is 12 inches in diameter, with a 4¼-inch face, and should be run at a constant speed of 300 revolutions per minute.



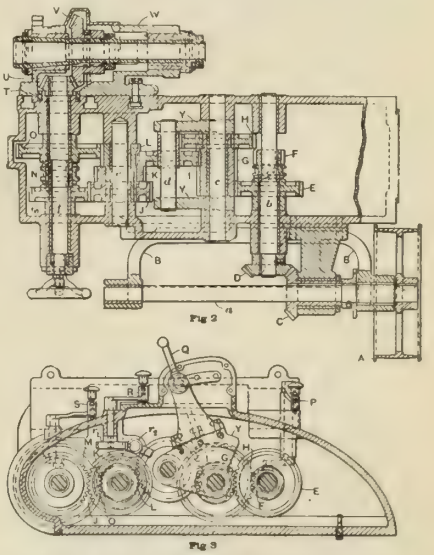


Fig. 1—Van Norman No. 3 Duplex Milling Machine, Waltham Watch Co., Springfield, Mass.

The feed change mechanism gives sixteen changes of feed, ranging from 7-16 inch to 13 inches feed of the table per minute. The drive to the feed-box is by a chain which connects with the main driving shaft. The table, which has a working surface of 45 by 10 inches, has a longitudinal feed of 30 inches, a transverse feed of 12 inches, and a vertical feed of 19 inches. The knee also has a vertical movement of 19 inches. The countershaft furnished with the machine has pulleys 13 inches in diameter and 4½-inch face, for forward and reverse speeds. The swivel vise, also included in the equipment, has jaws 7 inches wide, 1½ inch deep, with a maximum opening of 4½ inches. The weight of this machine is approximately 4,000 pounds.

Figs. 2 and 3—Spindle Speed Changing Mechanism.

PLAIN MILLING MACHINE.

The machine illustrated herewith follows in general outline the accepted usage of column millers, but has a number of features which tend to greater rigidity and strength as well as ease of operation. Substantiating the claim of the

manufacturers, that the machine is well adapted for high speed service.

The column which is cast in one piece has a considerable wider base than common, to resist the weight of table when at extremes of travel, a generous oil retaining rim surrounds this. The knee is of the box type, with extended top, and extra long bearing on column, is fitted with telescoping screw for elevation. The saddle is fitted with compensating stationary nut is very deep and inches long. The table has a great depth and

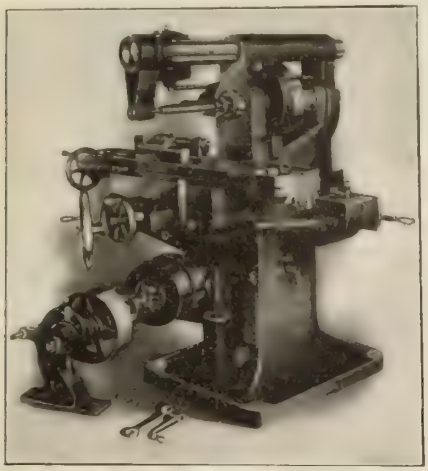

Fig. 1—Plain Milling Machine, Grand Rapids Machine Co.

a working surface of 32 x 8 inches with T-slots extending beyond oil pockets this gives additional space for fixtures, etc. in fact a 10 inch index outfit can be placed on same and allow full range of machine to be cut between centres. The spindle is of crucible steel and is bored for No. 10 B & S taper, and the cut shows the substantial journals as well as driving facilities consisting of a cone of three steps with a 12, 9 and 6 inch diameter for a 3 inch belt also back-gearing of 6½ to 1. When not back

Fig. 2—Phantom View of Feed Changing Mechanism.

geared the cone has four steps 12, 10, 8 and 6-inch. The feed gearing is of the selective sliding gear type. The phantom photos showing same to contain 13 steel gears of heavy pitch which gives 12 feeds.

Driving is accomplished with a nickel steel chain single lever feed control (also shown on phantom photo) operates by throwing lever to the side table should also move to. Pulling it forward disengages the feed.

The machine is fitted with a substantial arbor brace and is of the following range: table travel 24 inches, saddle

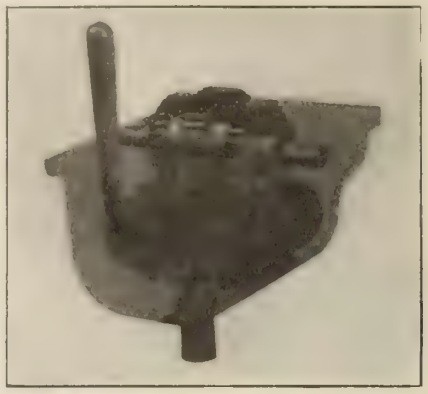

Fig. 3—Feed Controlling Mechanism.

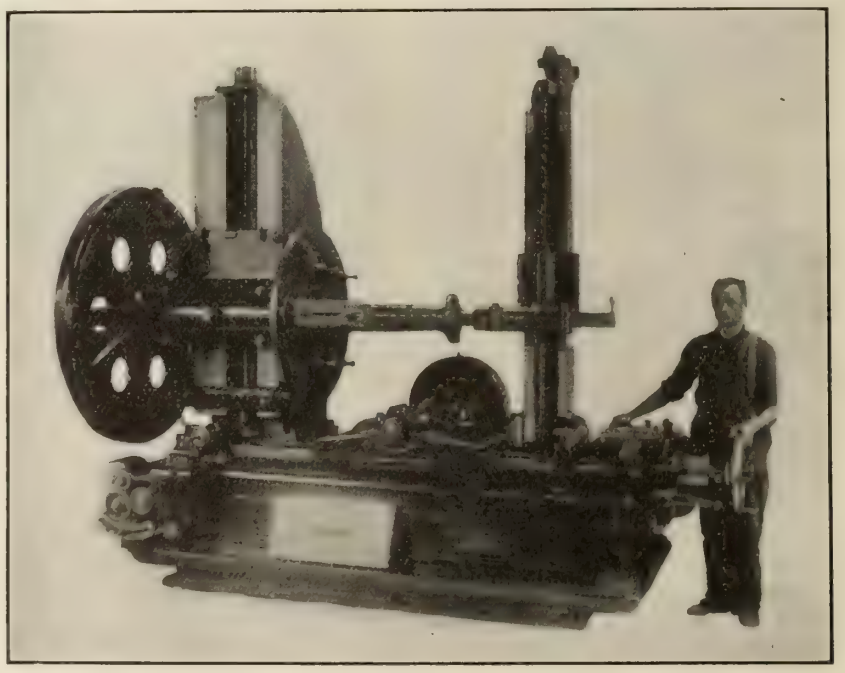
travel 8 inches and knee travel 18 inches. Net weight of machine is 2,020 lbs.

These machines are manufactured by the Grand Rapids Machine Tool Co., Grand Rapids, Mich.



GEAR CUTTING MACHINE.

The accompanying illustrations show an automatic spur gear cutting machine, manufactured by the Newark Gear Cutting Machine Co., Newark, N.J., for heavy spur gears. The machine has a capacity for gears up to 84 in. diameter, 24 inch face, and to cut 6 inches circular pitch.

The cutter spindle, crucible tool steel forging, is provided with a taper hole to receive cutter arbors. The cutter arbor is drawn into and forced out of the spindle, by means of a draw-in bolt, positively, without hammering. The spindle and arbor are amply heavy to secure the benefits of using a gang of finishing cutters, or a gang of finishing and roughing cutters side by side on the arbor. The spindle is driven by means of a powerful spur gear train. The various speed changes are obtained by means of change gears placed as near the last driver as possible. This allows the driving shafts to rotate at constant speed, and avoids undue strains in the shafts when the cutter is running at slow speed on heavy pitches.

The changes of the feed of the cutter carriage are obtained in similar manner, by means of change gears; but the rate of the cutter speed and the rate of the carriage feed are independent of each other, so that one may be changed without affecting the other. The carriage quick return is constant, not being affected by the feed or speed of the cutter. The carriage feed screw operates on the "draw-cut" principle, the thrust collars being placed so that the screw is not subjected to compression strains, either when feeding or returning the carriage. This draw-cut insures a smooth uniform feed to the carriage with freedom from vibration. The carriage also, as will be noticed in the photograph, is especially long, with the cutter spindle bearing in the centre of its length. This construction prevents chattering or vibration, and as the bearings are very long, with narrow guides, the action of the carriage is very smooth and quiet running, even when operating under severe duty.

The indexing or dividing mechanism comprises a large master wheel, and positive actuating mechanism. The master wheel is a worm wheel, generated in

Newark Gear-Cutting Machine.

place on each machine. It is made in sections, that is, a wheel proper, and a ring; this construction being used to insure accuracy not otherwise obtainable. The master wheel receives its movement through the positive indexing mechanism, which embodies a very simple clutch mechanism, requiring no adjustment. The various divisions for different numbers of teeth are obtained by means of change gears, which provide for cutting all numbers of teeth up to 100, and all from 100 to 450 except prime numbers above 100. A wide range of higher numbers can also be cut. Where any unusual number is required to be cut, this can be done by means of an extra change gear.

In connection with the positive indexing mechanism, is a safety device, which prevents the carriage from feeding until the division has been correctly completed. This is especially valuable when it is considered that the machine cuts very large and expensive gears. A safety mechanism also acts to prevent the machine from dividing when an obstruction on the gear blank, such as a lug or flange, would collide with the rim support, and otherwise, if it were not for the safety device, injure the gear or the machine. This mechanism is entirely automatic, and does not require any setting or adjustment, as it operates regardless of the size of the gear or the number of teeth being cut. It also is valuable, as though its interlocking feature, it prevents the operator from engaging the feed mechanism, while the machine is dividing.

The work spindle is of large diameter, machinery steel, accurately ground. It is provided with a taper hole, to receive work arbors; a draw-in bolt acting to draw the arbor in and force it out positively. The work head is of massive proportions, and is so gibbed to the head, that the alignment is maintained without regard to which of the clamping bolts is tightened first. The head is provided with screw and micrometer dial, graduated to read to thousandths of an inch. Power mechanism is provided for quick adjustment of the head, either up or down. The machine is very convenient, all the operating features being under the direct control of the operator.

DIXON'S STEEL CAR PAINT.

The Joseph Dixon Crucible Co., Jersey City, N.J., have just issued a very attractive little booklet of envelope size on their paint for steel cars. The booklet not only goes into the merits of the Dixon paint for this service, but illustrates a number of different types of steel cars upon which Dixon's paint has given excellent service. It also contains color chips showing the four colors in which Dixon's silica-graphite steel car paint is made. Anyone interested in steel car painting should send for a copy of this booklet which will be forwarded, free of charge.

TUMBLING BARREL.

The Globe Machine & Stamping Co., Cleveland, O., have placed on the market a new type of horizontal tumbling barrel for burnishing articles prior to plating, and for polishing either plated or unplated parts. The burnishing is effected by the use of steel balls. The barrel is of cast iron lined with maple wood and has an octagonal cross section. These machines are made with three sizes of barrels, the smallest of which is 24 in. in diameter by 8 in. wide, and the largest 30 in. in diameter with a width of 16 in. They are also furnished in either the single, double or triple-barrel types.

KILLING MOLDING MACHINE.

A molding machine of the jarring power rockover type has been brought out by E. Killing's Molding Machine Works, Davenport, Iowa. When the machine is being operated, the pattern is mounted on a pattern board and the whole is fastened to the rockover table. After the flask is in place and filled with sand, the mold is jarred to the proper density by compressed air, which is alternately applied and released automatically in the cylinder under the jarring table. Air is employed for this purpose and the pattern may be withdrawn at the speed which will give the best results. The jarring cylinder and the valve are simple in construction and the latter is of the expanding ring piston valve type. No springs are sued on this machine and all working parts are protected against the abrasive action of the sand.

NEW CORE RAMMING MACHINE.

The Norcross jarring machines manufactured by the Arcade Mfg. Co., Freeport, Ill., have been used extensively for ramming large cores. In order to make it possible to use a machine of this kind to better advantage a special type has been brought out and is primarily designed for ramming cores. It is shown in the accompanying illustration.

The total height of the machine is 15 inches. The piston is 8 inches in diameter and carries a table 24 by 30 inches. The piston travel in one-half inch and it will lift one thousand pounds. Under the table there is arranged a circular guide to keep the parts in line.

IRON AND STEEL BOUNTIES.

The bounties paid upon the manufacture of iron and steel expired on December 31, 1910.

In 1909 the bounty paid came to $1,808,533. This went in great part to the Dominion Steel Corporation, $1,029,503; to the Algoma Co., Sault Ste. Marie, $348,814, and to the Hamilton Steel & Iron Co., Hamilton, $238,408.

The rate paid in 1910 was 90 cents a ton for pig iron, 60 cents for puddled bars, and 60 cents for steels. Unless something is done at Ottawa these bounties will not be paid after this year.

CANADIAN ORE PRICES.

It is reported that the comparatively small block of Canadian iron ore recently contracted for by an eastern blast furnace for next year's delivery, was bought at close to 8 cents, delivered, per unit of iron at consumer's plant. From the standpoint of ore sellers, this is looked upon as a favorable price considering the grade of the ore disposed of and it tends to add weight to the expectation that foreign ores will probably sell at higher prices next season at eastern seaboard than the present year. Already it is understood German and English iron makers have contracted for large quantities of Swedish ore for next year's delivery, which on the same mine basis would make a pretty high price delivered at eastern seaboard.

Universally in the east there is a belief that the contracting in eastern domestic and foreign ores will not begin until late spring under present conditions of trade. It is certain that with curtailed operations the average eastern pig iron maker has more ore on his hands at this time than he had bargained for. Some contracts for domestic lump ore have been taken out freely and are puite well filled, but considerable furnace ore will be carried over until next year. Domestic shipments in November were not as heavy as in October, and this has been due largely to the activity of some consumers in the latter month taking in more ore than their actual needs in order to protect themselves against handling difficulties in winter.—Iron Trade Review.

According to the specifications of the United States Navy Department, high speed tool steel furnished to the department must have the following chemical analysis: tungsten, from 18.5 to 19.5 per cent.; chromium, from 5.25 to 6 per cent.; vanadium, from 0.1 to 0.35 per cent.; carbon, from 0.55 to 0.75 per cent.; the manganese content must not exceed 0.15 per cent.; silicon not more than 0.11 per cent.; phosphorus not more than 0.02 per cent.; and sulphur not more than 0.02 per cent. There must be no other impurities, and particularly not molybdenum.

COST CARD.

The Canadian Billings & Spencer Co., Welland, Canadian manufacturers of drop-forgings, have an excellent cost card system in use, brought from the home plant at Hartford, Conn.

The accompanying cut shows the form of card used. All the necessary data concerning size, cost, etc., of the article is embodied, and, in addition, similar information respecting the dies is given. From the information under "Dies," the method of manufacture can be seen, as the different kinds of dies and the numbers required of each are given.

In conjunction with this information a photo of the article, photographed beside of scale, is attached to the back of the card. This system is in more or less common use in the United States, in varied forms, but in forms somewhat differing from this one. It gives a complete record of the article, from material to details of appearance, in very convenient form.

LOWER BUSINESS TAX.

A Tax Reform League has been formed, Toronto is endeavoring to secure sufficient strength to influence the changing of the Ontario Assessment Act so as to allow municipalities to tax buildings, improvements, business assessments and incomes, at a lower rate than land values. The organization has offices at 75 Yonge St., and is sending out the following circular drawing attention to the objectional features of the present Assessment Tax :

"The business and income taxes of the present Assessment Act are especially objectionable.

"Under the income tax, the salaries of the officers of incorporated companies are taxed, while the incomes of the same persons under a partnership would be free. Thus the income tax is, in many cases, a penalty on a particular form of business organization.

"The business tax, since it is based on the value of the premises occupied, is really a double tax on buildings and improvements and penalizes the building of large, attractive and commodious premises, to the detriment of the employes, of the building trades, and of the general public.

"On the other hand, a moderate increase in the tax on the value of all land, whether used or unused, inclines the owners to meet the offers of those who desire to develop it, and when coupled with reduction of the building and business tax, results in an increase of all productive enterprise.

"So far from being a new, radical or revolutionary measure, the plan of allowing municipalities to reduce taxes on buildings, business assessments and incomes, has been tried for years in New Zealand, New South Wales, and our own Province of British Columbia with satisfactory results.

"This measure is eminently conservative, since it recognizes that conditions differ in different municipalities, and provides that each municipality may alter its system only after due consideration and on favorable vote of the ratepayers.

"We, therefore, commend this proposal to business men, in the hope that they will consider it in relation to their business interests, and support the demand for local control of local taxation."

In Toronto the Association have already secured the signatures of a large number of manufacturers in favor of this move, among these being :

R. E. Walker & Co., R. E. Walker ; Phillips & Wrinch, Chas. C. Phillips, president ; House of Hobberlin, A. J. Moreland, secy.-treas.; Jacques, Davy & Co.; Goldsmiths' Stock Co., Walter J. Barr, president ; Richard Southam, managing director Southam Press ; Hudson Co.; Farmers' Dairy Co., P. P. Farmer, Manager ; Noble Scott, printing ; Marshall Sanitary Mattress Co., Alan C. Thompson, mgr.; R. J. Hunter & Co., A. E. Brownlee, prop.; Frankel Bros.; Carswell Co., R. Carswell, general manager ; General Leather Goods Co., R. H. Cameron, manager ; National Leather Co., R. R. Corson, secy.-treas.

CENSUS OF CANADIAN MANUFACTURERS.

Archibald Blue, chief officer of the Census Department, Ottawa, gives notice that on June 1 next year a census will be taken of the manufacturers of Canada. It will ascertain the capital employed in works in 1910 along with the value of land, buildings and plant, the kind or class of products of the works by quantity or number of finished article and their value in the year. These statistics will relate generally to factories employing five hands or more during the year, but in such industries as flour and grist mills, brick works, saw and shingle mills, electric light and power plants, and a few others where the value of products is large in proportion to the number of persons employed, returns will be required without regard to the number of employes. The employes of work will include managers, superintendents, etc., on salaries ; officers, clerks, etc., on salaries ; operatives or workers classed as over and under 16 years on wages ; and piece-workers employed outside of the works. Salaries, wages and payments to all officers and employes will be entered on the schedule for the census year by sex, and will include the aggregate weeks employed in the year, average hours of working time per week, and aggregate wages paid to them in the year. The aggregate weeks of time and the aggregate wages paid will refer to the whole body of employes for the year while the average hours of working time will refer to an average computed for all employes in the year for one week only. The census of the dairy industry, relating to the production of butter, cheese, cream and condensed milk, will show for each kind of product its quantity and selling value, and the quantity of milk and cheese used for conversion at the factories, the number of patrons, and the amount of money distributed to them in the year.

LESSON IN EFFICIENCY.

W. R. Towne, president of the Yale & Towne Co., Stamford, Conn., states that by the use of scientific methods and automatic machinery, his company, within the past six years, has achieved increased output, decreased labor cost and increased wages to employes.

CANADIAN MACHINERY EDITORIAL INDEX.

Beginning with the January, 1911, issue the reading matter will be indexed separately from the advertising. This is done in order to supply each reader with a reference index at the end of the year.

SAFETY DEVICE CATALOGUES WANTED.

Kent McNaughton, Association Rooms, Stevens Building, Detroit, Mich., request catalogues from manufacturers of safety devices. He would like to receive as much literature on this subject as possible and therefore requests manufacturers whose catalogues show safety devices in connection with their own machines or apparatus to send him copies of such publications.

PERSONAL.

C. W. Lang, construction superintendent of the Dominion Coal Co., is leaving that position to engage in the service of the Brown Machine Co., New Glasgow, N.S., in which he has purchased an interest.

A. W. Wheatley, of the American Locomotive Works Co., Montreal, has assumed charge of the Brooks plant of the American Locomotive Co., succeeding John R. Magarvey, appointed manager at Schenectady, N.Y.

Clarence H. Booth, of Toronto, son of George Booth, president of the Booth-Coulter Copper & Brass Co., has been appointed general manager of manufacturing for the E.M.F. Co., of Detroit, to succeed David Hunt, Jr.

A. C. Hanna, formerly secretary of the Dominion Wire Co., Montreal, has gone to Winnipeg as sales manager there of the Steel Co., of Canada.

RECENT ADVANCES IN G. T. R.

Several important changes have recently taken place in the management of the G.T.R. shops at Battle Creek, Mich., Montreal and Toronto. J. C. Garden, master mechanic of the G.T.R. shops at Point St. Charles, Montreal has been transferred to a similar position in the new shops at Battle Creek.

J. J. Duguid, formerly general foreman of the Toronto shops, has been advanced to the position of master mechanic of the G.T.R. Eastern Division. Mr. Duguid's former position is filled by William Sealey, formerly foreman of the erecting shop, Stratford. Mr. Sealey is succeeded by W. Davis, formerly chargeman. Mr. Davis is in turn succeeded by J. Hollingsworth.

WINNIPEG RAILWAY CLUB.

At the last monthly meeting of the Western Canada Railway Club, held at the Royal Alexandra, Winnipeg, the feature of the evening's proceedings was a paper on "The Training of a Railway Employee," delivered by H. Martin Gower, superintendent of apprentices for the Canadian Pacific Railway at Montreal. The paper, which was of some length, dealt with the necessity for technical education, gave many statistics on the matter, and adduced suggested lines of systematized training. It was well received by the members present, about 100 in number, and a discussion followed.

CENTRAL RAILWAY CLUB.

The regular meeting of the Central Railway and Engineering Club, Toronto, was held on Dec. 20, when Gordon C. Keith, managing editor of Canadian Machinery, read a paper on "Modern Machine Tool Practice for Maximum Production."

The following officers were elected for 1911: President, G. Baldwin, yardmaster, Canada Foundry Co., Toronto; 1st vice-president, G. Bannon, chief engineer city hall; 2nd vice-president, A. Taylor, foreman boiler maker, Polson Iron Works.

Executive committee: A. E. Till, foreman C. P. R.; E. Logan, machinist, G.T.R.; C. G. Herring, chief draftsman, Consumers Gas Co.; A. E. Wilkinson, Lunkenheimer Co.; A. M. Wickens, chief engineer Canadian Casualty and Boiler Insurance Co.; W. E. Cane, supt., Chapman Double Ba" Bearing Co. and A. J. Lewkowicz, consulting engineer, Universal Gas Co.

Auditors: J. Herriot, general storekeeper, Canada Foundry Co.; D. Campbell, storekeeper, Consumers Gas Co., and A. W. Durnan, of Rice Lewis & Sons.

CLAY PRODUCTS ASSOCIATION.

At the annual meeting of the Clay Products Manufacturers Association held in Toronto recently, the election of officers for the ensuing year took place as follows:—Pres., Robert Davies, Toronto; First Vice-Pres., D. A. Lochrie, Toronto; Second Vice-Pres., W. H. Freeborn, Brantford; Third Vice-Pres., David Martin, Thamesville; Sec.-Treas., D. O. McKinnon, Toronto.

TANNERS' SECTION B. OF T.

The officers elected at the recent meeting of the Tanners' section of the Toronto Board of Trade are:—

J. J. Lamb, chairman.

F. B. Clark, vice-chairman.

F. G. Morley, secretary-treasurer.

Executive committee—J. C. Breithaupt, S. R. Wickett, W. D. Beardmore, George McQuay, C. G. Marlatt, Geo. P. Beal, George C. H. Lang, A. O. Beardmore, Charles King, A. R. Clarke, E. J. Davis.

Legislation committee—Chas. King, S. R. Wickett, A. R. Clarke, George P. Beal, A. O. Beardmore, Hon. E. J. Davis, R. M. Beal.

Transportation committee — J. C. Breithaupt, C. G. Marlatt, S. R. Wickett, John Sinclair, Geo. C. H. Lang, W. D. Beardmore, A. O. Beardmore, R. M. Beal, Charles King, A. R. Clarke, E. J. Davis. Representative to council, A. O. Beardmore.

WINNIPEG MACHINISTS ELECT OFFICERS.

The International Association of Machinists, lodge 122, Winnipeg, held its annual election of officers on Dec. 7. Great interest was manifested and a large proportion of the membership, which is now upwards of 300, took part in the proceedings. The result was as follows: A. Sturrock, president; S. Holliday, past president; G. Johnston, vice-president; H. F. McDonald, recording secretary; D. McCallum, financial secretary; A. Robertson, treasurer; S. Miller, constructor; C. Cross, sentinel; E. McGrath, R. F. Shore, and D. McCallum, delegates to trades and labor council; S. Holliday, J. Muir and E. Emerson, delegates to federated trades council. A committee consisting of H. F. Macdonald, S. Miller, H. M. McGregor, A. Young, J. Addison, W. Patterson, D. McCulloch, and J. C. Mountjoy, was appointed to make arrangements for the annual entertainment which will be held early in 1911.

TORONTO MACHINISTS ELECT OFFICERS.

Toronto Lodge 235 of the International Association of Machinists elected officers for 1911 as follows: President, W. Hagan; vice-president, J. Waphott; recording secretary, R. McDonald; financial secretary, T. A. White; treasurer, W. Dill; conductor, Wm. Gravell; inside sentinel, E. Cole; executive committee, J. McNaulty, Newton Henders, T. Burgess, J. Blugerman; auditors, D. Montgomery and W. Singer; trustee, Thomas Walsh; business agent, L. H. Gibbons.

The general solution of the problem of industrial education must be by means of public industrial schools, where such fundamentals will be taught as will prepare boys and girls for the industries of the surrounding territory —remembering that the aim and end of all education is to train men and women to think.

POWER GENERATION AND APPLICATION

For Manufacturers. Cost and Efficiency Articles Rather Than Technical.
Steam Power Plants ; Hydro Electric Development ; Producer Gas, Etc.

BELT PULLEYS.

By Peter Bain, M.E.

IN the selection of power transmission equipment, much consideration is given to power saving ; but while the prospective buyer is sacrificing time and money, investigating the more or less expensive devices that come under this head, he invariably overlooks the great saving that can be effected by a careful selection of pulleys.

Pulley Factors.

In determining what pulleys are best to use in any equipment, the factors of windage, weight, balance, belt contact, powerful compression to avoid keyseating of shaft, and convenience of handling, should have prime consideration, as affecting economy of power in subsequent service. A choice of pulleys which fulfills these requirements may mean a somewhat higher initial outlay, when compared to a choice made without regard to anything, save suitability of diameter, pace, hose, etc., but will mean annually, however, a much reduced operating expense in comparison. To save much time and annoyance later, it is advisable to have all pulleys in halves, facilitating as it does, replacements often hurriedly required.

Comparison of Pulleys.

Pulleys as manufactured, are of cast iron, wrought iron, mild steel, wood and iron or steel in combination with wood, the shaft bushing perhaps being more or less common to all. Iron pulleys of all kinds show a distinct loss of power, when compared with those in wood, due to belt slippage, and amounting in accordance with test and experiment to as much as 50 p.c. Wrought iron or steel pulleys with perforated rims do not show so unfavorably as those in cast iron. For good belt contact, minimum slippage, and least power absorbed without recourse to belt dressings to secure adhesion, the wood rim is to be commended.

Belt dressing should only be used to keep belts pliable, and not to keep them from slipping. Its use for other than the former purpose, shows faulty installation and want of attention on the user's part.

Cast iron pulleys again are objectionable on account of weight, and require in this respect, compared with wood pulleys, more power to operate, while as favorably placed regarding windage. Wrought iron pulleys while light, and attractive as regards windage, do not give satisfactory balance, especially when split, and are not on the same plane as a properly designed wood pulley.

It must of course be borne in mind that there are good and bad features in wood pulleys. Belt contact, reduced weight, and facility of handling, are generally speaking strong points in their favor, but unless at least the equivalent windage of a well designed cast iron pulley be had, the other gains may be almost all offset. The properly designed wood pulley should be the equal of other types in their best features, and their superior otherwise.

Windage.

An absence of windage is not always a feature of wood pulleys, a circumstance unfavorable to their more universal adoption, and responsible for their career being prematurely closed in many installations. The elimination of this difficulty is not insurmountable, and already much has been done, so much in fact, as to bring the wood pulley windage on a par at least with that of the best in cast iron pulley design, and putting it in a class by itself for cheap operating cost in power transmission, with an ultimate influencing of its larger adoption. The improvement necessary in the reduction or absence of windage in wood pulleys, lies in the arm attachment between rim and hub. To get equal results, the arms should be of a shape corresponding to those of cast iron or somewhat similar, the material light, rigid, reliable, and attached securely to rim and hubs. Arms of cold drawn seamless steel tubing, pressed into ribbed form, and forced into a taper hole on bases of a malleable iron hub, these upset and headed over on end, constitute a fastening which has come under the writer's notice as having much to recommend it. The arm and rim attachment is housed within the rim, and consists of a saddle piece embracing the flattened end of arm, and fastened to it by steel pins driven into rim.

Belt Pulley Speeds.

The wood pulley has advantage over those of iron or steel, in that it can be run at a much higher speed, ordinarily three times as fast, while experience shows that it is impracticable to run pulleys of iron or steel for mill and factory purposes at greater rim speed than five to six thousand feet per minute, roughly one mile per minute. As showing what can be done, a wood rim pulley with iron spider has recently been made and tested by the Dodge Mfg. Co., to run safely at five and one-half miles per minute. Such a result is intensely interesting, and serves to emphasize the benefits to be derived from a more extensive use of well designed wood pulley equipment.

Shaft Attachment.

The shaft attachment of pulleys is a matter of some importance, necessitating as it does, the cutting of the keyways, the use of set screws, or reliance on the compression of the bushing alone.

Solid cast iron pulleys invariably require keyseating of the shaft, the only exception being for very light loads. No keyseating means a reduction of outlay, a rapid convenient attachment, and an unimpaired shaft strength. It must never be forgotten that keyseating a shaft reduces its strength at that point, and in the case of cold rolled shafting, much of which is used in power transmission, and which depends on its unbroken surface for maintenance of comparative strength, keyseating is highly detrimental, placing it inferior to turned shafting under the same treatment.

Hurry jobs call for easy yet effective fixings, and cold rolled shafting and keyless pulleys do much to help out awkward situations.

Hub Bushings.

Cast iron bushings with large bearing surface are best adapted for all pulleys, because when properly compressed, they exert a positive contact with the shaft. The adaptability to compression depends much on the elasticity of the hub material, and a malleable iron hub, light yet strong, seems to give with the cast iron bushing, results hard to surpass in the matter of keyless shaft attachment.

Conclusions.

The belt pulley question is of wide interest, and does not have that importance in the estimation of large and small users (the latter particularly) that it should. With the various manufacturers there lies the looked for improvement in pulley development, which will give the user a highly efficient service and convenience, leaving first cost if high, to be justified by ultimate operating results.

G. P. & H. ELECTRIC LOCOMOTIVE.

THE accompanying illustrations show two views of the new electric locomotive recently purchased by the Galt, Preston and Hespeler Street Railway Co. This company operates some 30 cars on a standard gauge interurban line, 21 miles in length, connecting the above points with the towns of Freeport, Centreville, Berlin and Waterloo. The power station and repair shops are located at Preston. The railway traverses

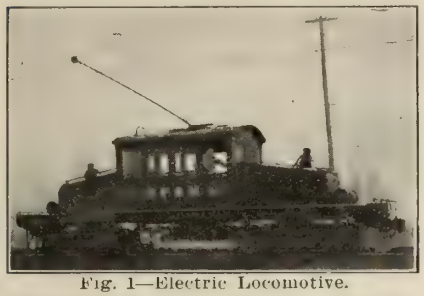

Fig. 1—Electric Locomotive.

a farming country and does a thriving business in both local and through passenger and freight service.

Several years since the G. P. & H. Ry. Co. purchased from the Westinghouse Electric & Mfg. Co. a quadruple equipment, consisting of four No. 93-A direct-current motors with a nominal rating of 60 h.p. each at 600 volts, for a locomotive similar to the one shown, but of smaller capacity. Its operation has been eminently satisfactory in every respect and the recent order for a larger locomotive of the same general characteristics argues strongly for the excellence of design and low maintenance charges of this type of slow speed freight locomotive.

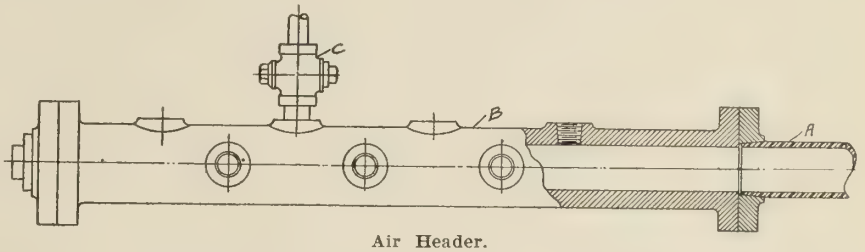
Much has been said about the impracticability of electric freight haulage but the steadily increasing sales of slow speed electric locomotives especially designed for freight service and the invariably favorable reports of operation is affirmative evidence of the most forceful nature. There are many interurban electric roads tapping sparsely settled farming districts and outlying towns not favorably located on main steam trunk lines, which could develop a highly profitable express and freight traffic with the aid of a suitable electric locomotive.

The G. P. & H. locomotive shown was built by the Baldwin Locomotive Co., and the complete electrical equipment furnished by the Westinghouse Electric & Mfg. Co., Pittsburg. It is designed for the standard 4 ft. 8½ in. gauge and provided with double swivel trucks. The wheel base is 29 feet and the overall dimension 36 feet and it weighs complete, 100,000 pounds. The gear ratio of 16.57 gives a normal speed of 8.25 m.p.h. at which speed a tractive effort of 18,200 lbs. is developed. The maximum tractive effort is 25,000 lbs. The locomotive carries a quadruple equipment consisting of four No. 308-B-2 interpole direct current railway motors having a nominal rating of 100 h.p. each, or a total of 400 h.p. at 600 volts. These motors are fitted with special windings adapting them particularly for slow speed locomotive service. Standard nose suspension is used.

The Westinghouse unit switch control was provided. Two master controllers are supplied one in each end of the cab. These controllers carry only the very small current from a storage battery, for exciting the electro-magnetically actuated needle valve which admits air at 70 lbs. pressure to the air cylinders of the unit switch. The action of each switch is therefore positive and independent of fluctuations of the line voltage. It not infrequently happens on interurban and stubend lines that the voltage at points far distant from trolley feeders is as low as 200 volts when the motors are in operation. Under such extreme or even less severe conditions solenoid operated contractors, depending upon the line voltage for their contact pressure, are very apt to give trouble due to looseness and arcing at the contacts. With air operated switches all such possibilities are eliminated and the greatest reliability under all conditions assured.

Fig. 2 shows this locomotive hauling a loaded train weighing 1,040 tons on the experimental tracks of the Westinghouse Co., near Trafford City, Pa. This was the heaviest load available at the time, though it was evident that under similar conditions the locomotive would have handled a 2,000 ton train with equal ease.

Fig. 2—Electric Locomotive, with Normal Draw Load.



OXY-ACETYLENE CUTTING.

Recently the bridge over the Don river, Toronto, was moved to make room for another structure. It was necessary therefore to cut the 16 in. water main, which was suspended underneath the bridge.

Instead of adopting the old method of cutting the pipe with a hard chisel, or boring a number of holes and then sawing it through, the task was accomplished by means of an oxy-acetylene flame. The Davis-Bournonville system was used under the direction of Mr. Fennel. When the flame was turned on the ⅝-inch metal it rapidly bit into it. This operation was completed inside of fifteen minutes. A second cutting had to be made some eighteen inches further back to take off a section of the pipe, to prevent it catching on the abutments when the bridge was moved. The operation had to be conducted at both ends of the bridge, and the whole work was accomplished inside an hour.

AIR HEADER.

The accompanying cut shows a convenient form of header for use in distributing compressed air from air mains, where the number of tools at any particular spot are more than two or three.

Air Header.

This header permits of eight lines of hose being taken off from the one spot, and is a device found very convenient in the shop and yards of the Collingwood Shipbuilding Co., Collingwood, Ont., especially when constructing the boat on the ways, as a multitude of pneumatic hammers, and drills are in use.

Pipe A is connected by a T to the air main. The header itself, B, is a cast iron body with two sets of holes at right angles, staggered, thus facilitating hose connections. From each of these eight bosses on the header, the hose pipes lead out, with an independent valve, C, on each. The pipe A may be given a valve as well, permitting of the shutting off of the whole head.

CANADIAN MACHINERY
AND MANUFACTURING NEWS

A monthly newspaper devoted to machinery and manufacturing interests mechanical and electrical trades, the foundry, technical progress, construction and improvement, and to all users of power developed from steam, gas, electricity, compressed air and water in Canada.

Vol. VII. January, 1911 No. 1

EFFICIENCY OF RAILROAD SHOPS.

Discussing the paper on "Modern Machine Tool Practice for Maximum Production," read before the Central Railway and Engineering Club, C. A. Jefferis, General Superintendent of Consumers' Gas Co., Toronto, said that the mechanic in the ordinary small shop was not as fully acquainted with the developments in machine tools and high speed steels as the one employed in a railroad shop. This is a very important statement in view of the fact that the daily papers and others would have us believe that the railroads are wasteful, uneconomical and unscientific. Supporting this latter view, Louis D. Brandeis, representing the eastern shippers before the Interstate Commerce Commission, declared the railroad methods lacked technical skill and scientific accuracy, that by the application of these the cost of operation would be enormously reduced. The rigid economy of scientific methods forced upon ordinary industries by the pressure of competition, has not, according to Mr. Brandeis, developed among the railways to a proportionate extent.

The argument can be answered by one of his own references. He cited the case of the Santa Fe railroad, giving figures showing that in six years a saving of $5,800,000 was effected by improvements in methods.

The Santa Fe railroad is a most progressive one, as are also such railroads as the New York Central, Canadian Pacific and Grand Trunk railroads. As for the car, locomotive and repair shops of these railroads, the methods are both scientific and economical. Men are technically trained under the supervision of the companies. Apprenticeship systems with educational classes are features of the four above mentioned railroads. The result is that railroad practice is modern in every particular.

When high speed steel was introduced the railroads were among the first to take hold of it. The machine tools used in railroad shop practice have developed to such an extent that the companies are waiting for some genius of the Taylor type to develop a still better steel than that with which we are now acquainted. The railroad shops of the G. T. R. at Stratford, Ont., and Battle Creek, Mich., and the C. P. R. Angus shops at Montreal are examples of the result of trained minds seeking the best shops and equipment procurable.

While the railroads are not responsible for all the improvements in machine tools, still the manufacturer using metal working machinery should keep watch on the methods of the railroads. They are always ready to give anyone desiring it the benefit of their experiences. In almost every issue of Canadian Machinery railroad shop methods are given, showing the trend of modern practice in railroad shops. While the various industries have been making improvements, the railroad shops, too, have been keeping pace with the advances in the mechanical field.

COMMON COURTESY.

That common courtesy pays is beyond a doubt, whether in the shop or office. The apprentice and workman owes it to his foreman as also does the foreman to those under him. A foreman is responsible to the management for the workmanship and behavior of the employes. His instructions should be carried out carefully. The foreman is the medium through which a workman secures advancement, and be sure he will assist the man who is square and courteous to him.

Then the management will secure loyal foremen and workmen by being courteous to the employes. They must depend on the men to turn out good work, and when treated with consideration, the management need never be ashamed of the workmanship.

There is still another point. Those entrusted with correspondence should be courteous. Brevity is being aimed at in all business correspondence, but do not let the shortness of the letter prevent it being courteous. A letter should be written so that a favorable impression is at once created. Be sure a study of common courtesy in letters will result in making friends and securing business.

HEALTH AND CARE OF EMPLOYES.

The health of employes in manufacturing establishments constitutes a factor in economical production which is highly worthy of consideration. The workman who has to be absent a part of the time because of bodily ailment must necessarily upset shop routine; if his work is highly specialized, so that it is difficult to fill his place temporarily, the result may be serious in disturbing the balance of manufacturing. Even if a man continues his employment despite impaired health his usefulness depreciates perceptibly.

Progress in shop sanitation has of late been rapid. Good light, ample ventilation, better heating apparatus and approved toilet conveniences have been carefully provided. Manufacturers have kept pace with the general movement to better the condition of those whose days must be spent in factories. Environments have been made satisfactory in most trades, and reading, rest and lunch rooms have been provided.

An excellent beginning in the direction of looking after the health is being made in the public schools by instruction in the hygiene of the body and by a system of medical and dental inspection. Many cities employ physicians to inspect the schools regularly for cases of

sickness, defective hearing and sight, etc. In a few places high class dentists are provided to make compulsory examination of the teeth of children and to furnish treatment free of charge or at small cost. If this system spreads through the country, as it is believed it will, the workman will be blessed. It is advocated that the education of employees, especially of young persons, in this direction would bear profitable fruit.

In a small way this sort of work is aready going on. The foreman who takes an interest in those under him will advise skilled treatment for any trouble that comes to his attention, especially if it causes the employe to lose time. It is confidently prophesied that the general modern movement will go much farther than the point it has now reached, as the employer assumes a more direct interest in his working people, impelled by the combined motives of human kindness and the practical business advantage that comes with the services of employes in the full possession of their health. If this condition is brought about it will be but following along the same line as that of the shop surgeon of the present day, a side of industrial management which is becoming common, and which is supplemented in large works by well equipped private hospitals. Already in the United States, says The Iron Age, there has grown out of this practice the employment of a regular shop physician who looks after employes when they are ill as well as when they have been injured. The best of the cotton mills of the South are said to have adopted this system as a most important element in keeping together their communities of workers.

There is also the work to the injured. In a number of Canadian industries branches of the St. John's Ambulance Association have been formed. On December 21, 1910, an Ontario branch of this association was instituted, a Dominion branch having been formed Feb., 1910. Branches have been organized in the east and western branches will now be formed.

A branch of this association was organized some years ago in the works of the John Bertram & Sons Co., Dundas, and in the C. P. R. Angus Shops, Montreal. In the latter shop it has been found to work so satisfactorily in giving first aid to the injured, that it is being extended along the whole system from coast to coast. S. A. Gidlow, the general secretary, has been establishing classes in the various shops with this in view. The objects of the association as pointed out in Canadian Machinery some months ago are:—Instruction in "first aid," and prompt assistance to those suffering from accident or sudden illness, instruction in the use of stretchers, hygiene, sanitation and relief of sick and injured.

Special attention is paid to accidents in the shops. During the six months ending July 31st last there were 2,033 industrial accidents officially reported in Canada, 656 of which were fatal. There are in Canada annually 3,000 deaths from accident, and it is estimated that there are 17,000 accidents which are not fatal. There is no doubt that many lives would be saved, much suffering lessened if the principles of first aid to the injured were generally known, and good use made of the precious minutes before the doctor arrives.

The whole matter is a question of shop economics. It is certainly to the advantage of industrial establishments to have contented, healthy men employed. And when accidents do occur, as they will sometimes in the best shops, the saving of the life of an employe or the giving of first aid assistance which will hasten his recovery and return to work, will unodubtedly help in making loyal, contented, healthy employes, who will serve the employer faithfully and with the best of his ability.

HAVE SUFFICIENT EQUIPMENT.

The writer entered a good sized shop recently, and as he passed through the shop he heard one workman greet another: "Say, Bill, let me use your vise a minute." Investigation showed that all the vises were constantly in use, and that there was considerable changing around to allow another to use a vise.

It would be interesting to calculate the cost of keeping men standing around waiting for a vise while another used it. It would not take many days' savings to pay for that vise. By not providing sufficient the price of quite a number will be lost in a year.

The question of wasted time should always be kept in mind. A careful study should be made of the requirements, and in the selection of a number of vises, or in the choosing of drills or other machinery, the elimination of unnecessary waste in the handling of work should be kept constantly in mind. It will be found, if this is done, that the cost of production will be greatly lowered.

TOPICS OF THE MONTH.

From time to time we receive letters from friends of Canadian Machinery telling how Canadian Machinery had helped them. Our circulation representatives are met courteously and assisted in interesting others in the paper. As an instance of the usefulness of Canadian Machinery to superintendents and foremen, we cite the following:

A foreman in one of Brantford's up-to-date machine shops told a represntative that he found Canadian Machinery invaluable. In order to illustrate how he made use of the paper, he described a job somewhat out of the ordinary, that came into the shop recently. He remembered seeing a similar job described in Canadian Machinery some time before, and as he kept a file of them, he readily hunted up the article which was in the "Methods and Devices" Department, and completed the work without difficulty.

• • • • •

Beginning with the present issue of Canadian Machinery, a series of articles will appear monthly, touching the selection, installation, operation and efficiency of power transmission equipment. Every effort will be put forth to make the treatment of the various subjects popular and helpful to our wide circle of readers, users and operators. Power transmission is inseparably connected with manufactures of every description, and has in consequence a large claim to attention. The subject this month is "Belt Pulleys," to be followed in our February number by Rab on "Belts and Belt Drives."

SEASON'S GREETINGS.

IN the year that has passed we have made many new friends among superintendents, master mechanics, foremen, students and men interested in mechanical pursuits. Old friendships, too, have been strongly cemented, and we take this opportunity of expressing our cordial wish that the New Year on which we have entered may bring you great happiness and unlimited prosperity.

The Editors and Managers.

January 1, 1911.

FOUNDRY PRACTICE AND EQUIPMENT

Practical Articles for Canadian Foundrymen and Pattern Makers, and News of Foundrymen's and Allied Associations. Contributions Invited.

SKELETON AND SWEEP PATTERNS

By F. S. Cubbige.

When only one casting or a very few castings are required, a skeleton pattern is used or the mold is swept up by means of sweeps.

In Fig. 1 a skeleton pattern for a pipe bend is represented. First two boards are sawn out the shape of the pipe, and extending past the flanges to include the core prints, these pieces are doweled together, then circular pieces are sawn out to make up the diameter of the pipe at from 2 in. to 8 in. apart along the full length of the pipe and core prints. The flanges b b are cut out to fit over the boards a a. A strike or strickle is made the diameter of the pipe for the body, and one smaller in diameter to suit the core prints. The molder completes the pattern by filling in between the circular pieces c c c, with green sand and striking off any projecting portions of sand by means of the strickle D, and covering it with parting sand and then it is ready to be used as an ordinary wood pattern.

The core for the skeleton pattern is generally just swept up with a strickle, using a flat board cut out parallel to the

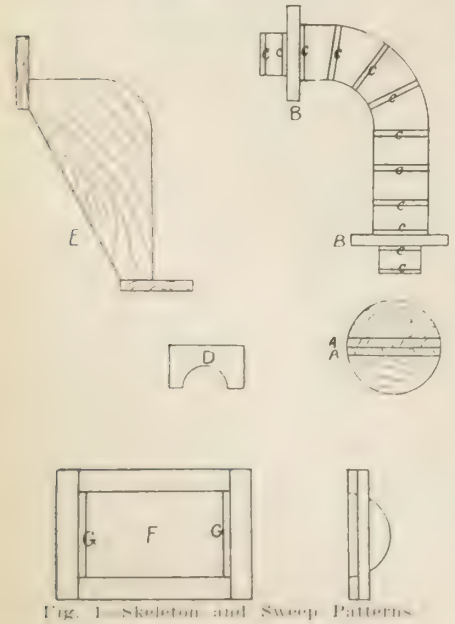

Fig. 1.—Skeleton and Sweep Patterns.

inside of pipe and strickle cut out to the diameter of the core. The board is fastened to the core plate and the core sand built on the plate so that it may be strickled, as shown at c, Fig. 1.

When making a skeleton pattern and core frame for a straight piece of pipe, the pattern is made on the principle shown in Fig. 1, a, but the core frame is generally made as shown in Fig. 1, f, and a straight strickle used over the half-circles g g, making one-half core at a time on a core plate.

When a boss or small inlet or outlet is required, a piece is turned the required shape and is secured to the circular pieces on pattern at the place where it is wanted and the green sand filled in under it between the sections. Or if an inlet or outlet piece is required on the inside of the pipe a straight piece is screwed to the ends g g, and the boss or pipe inlet or outlet, as it may be, is secured to it and the core built up and strickled the same as previously described.

In making very large pulleys or flywheels, they are very often swept up by means of sweeps, the arms and hubs being made in a core box.

Take a pulley having six arms, as shown in Fig. 2, a core box is first made for the arms. This box must be at least six inches wide, as it requires 6 in. for the one-sixth part of hub, which is included in the core box, as shown at c, Fig.2 (b) D being half of pulley arm.

It is next necessary to make a section of the rim of the pulley about 2 to 3 ft. long, the flauges E E, Fig. 2 A being screwed on. Two pieces of 1 in. stuff about 4 in. wide are then secured to rim segment, as shown in elevation, Fig. 2 (D). The distance f being the radius of the pulley required. In molding this pulley the molder first sweeps up a flat bed, a hub 12 in. diam. and 2½ in. deep is then placed in the centre and the sand built up around it, out to within about 6 in. of the outside diam. of wheel and swept level, then the hub is drawn out and the arm cores are set on the green sand, the two half-cores to make a complete arm having been pasted together. A spindle or shaft is next driven into the centre of the mold, to be used as a guide to use sweep (D) Fig. 2, the sweep being connected to spindle by means of the hole H in strips E E, Fig. 2 (D).

The sweep is then set in position and the sand rammed in from the sweep segment to the hub of pulley and up to the top of sweep at rim and to top of arm cores at centre of mold, then the sweep is moved its own length, less an inch or so around, and the operation repeated until the inside is rammed up and then the pieces E E are removed and the sand rammed up all around the outside. The sweep pattern and spindle are then drawn out and cake cores set all around the top of the rim and a core to form the top of hub is made and set on and the mold is finished. Of course, the molder has to make his own provision for gating and venting, etc., but as we

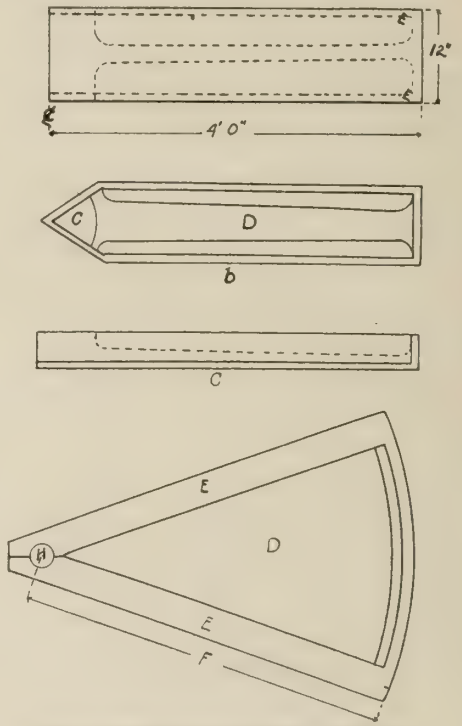

Fig. 2.—Skeleton and Sweep Patterns.

are only considering pattern work we will leave that part alone.

VANADIUM STEELS IN LOCOMOTIVE PRACTICE.

Several foundries are now specializing on vanadium steel castings for locomotive work, and in the past three years have turned out a large tonnage not only for frames, but for driving wheel centres, cross heads, cylinders, and other parts in which dynamic strength is particularly desired.

Several of the large railroad systems specified several years ago vanadium cast steel frames in a small way for trial, and are now specifying it as a standard on all new equipment. Another large system had much trouble from front end failures, but is said to have overcome the difficulty by substituting vanadium cast steel front ends with change of section.

One of the large railroad systems of this country was having an excessive number of failures of wrought iron frames and the shops were with difficulty keeping the engines in commission.

It was decided to replace sections of the wrought iron frames in the zone of breakage by pieces of vanadium cast steel welded into place. It is said that these parts never broke, but that in the same frames breaks subsequently occurred in the original wrought iron portion. Other vanadium steel sections were then welded in, and gave no trouble. It was later decided to make the entire frame of vanadium cast steel, and the service from these frames was so satisfactory that for new locomotives vanadium cast steel frames were specified.

INJURIES AND DISEASES OF MOLDERS.

The Giesserei Zeitung discusses the possibility of injuries that lie in the tapping of furnaces, transporting and pouring of molten metal, spattering and sputtering of metal, and in the breaking of cranes, conveying apparatus and cleaning of castings. The article has been translated by Castings and is reproduced herewith. If molds are not dried sufficiently, possibility of explosion enters in touching molten iron with water. This is increased by the poor lighting found in so many foundries, and the fact that near closing time more haste and less care is used by workmen. Blowing powdered carbon and coal dust on molds, envelops workmen in coal dust, while cleaners are surrounded by clouds of burned sand and coal dust or carbon when cleaning castings.

There is also the formation of gases near cupolas and influence of heat radiation. The cupola gases contain from 15 to 17 per cent. CO, and 10 to 15 per cent. carbonic acid. Usually cupolas lie at an outer wall of foundry, and the tapping hole is inside of shop, charging door is outside and a little higher. Charging should never be done directly, as insufficient ventilation and escape of gases may cause diseases through the poisonous gases. If in such an atmosphere the workman has to carry heavy charges, due to lack of mechanical conveyors, his vitality to resist these gases is lowered to the danger limit.

To avoid inhalation of dust in cleaning castings, a sand-blast with suction device is best for use. With very large castings a pneumatic scraper might be used instead. In either case, suction devices should be near cleaning tables to suck in dust at once.

Statistics for pourers and molders in German foundries show that from 40 to 50 per cent. suffer from diseases. Among these are diphtheria, tonsilitis, acute rheumatism, heart diseases, acute indigestion, acute and chronic bronchitis, and tuberculosis. Besides, they show a larger number of sufferers from eye troubles, burns, poisonings and kidney diseases. The death rate is not quite as high; causes aside from tuberculosis, being chronic kidney diseases and suicide.

In preventing burns on the feet the foot-gear plays the main role. Out of 247 cases of burns due to molten metal, 58.7 per cent. went on laced shoes, and 16.6 per cent. on low shoes.

Sommerfeld in his investigations found that out of 100 deaths and sicknesses in foundry workers, 62.5 per cent. came on organs of respiration of the pourers, 60 per cent. of cleaners. The average age of the former is 45.9 years, of the latter 48 years, showing both branches of foundry work to be equally unhealthy.

Rooms for cleaning castings should be lofty, light, broad, artificially ventilated. In winter the room for molders should be heated, as they are especially exposed to colds, handling cold and wet material. A number of accidents can be lowered if molds are not placed too closely and enough space is left between them for passage. Cleaners should wear masks or at least protection goggles. Where no suction is provided in cleaning of castings, workmen should have small respirators to prevent lungs from inhaling dust. Frequent use of soap and water should also be impressed on workmen.

PNEUMATIC TESTS OF PIPE.*

By William R. Conrad.

LAST spring two separate corporations wishing to put in some pipe lines that would be absolutely tight when laid and in service, ordered from two separate manufacturers a quantity of cast iron pipe, each purchaser specifying in addition to the usual hydrostatic test that each pipe be carefully tested with air, compressed to 50 pounds per square inch, and that while under this pressure soap and water suds be applied so as to reveal open or porous iron or defects which the hydraulic test had not developed. Because of this additional test and it being known that air will, when compressed, work through metals more rapidly than water, it was determined by the manufacturers to use nothing but the best grades of iron that would give a close and uniform texture.

The results were that in one case there were 4,954 pipes tested either hydrostatically or pneumatically; of this number 27 leaked under hydraulic pressure and 272 leaked under pneumatic pressure, those leaking under pneumatic pressure having already passed the hydraulic test; this makes a percentage of leaks of the whole quantity tested 0.545 of 1 per cent. for the hydraulic and approximately 5.5 per cent. for the pneumatic, or slightly over 6 per cent. for the two tests. In the other case there were 2,737 pipes tested, of which 14 leaked under hydraulic and 186 leaked under pneumatic pressure, the percentage being 0.511 of 1 per cent. for the hydraulic and approximately 6.8 per cent. for the pneumatic, or about 7.3 for both. Analyzing further, you will notice that the percentage of hydraulic leaks to the total number was but about 6.2 per cent. of the total number of leaks, taking both jobs together. This proportion, however, would undoubtedly have been more evenly divided had the hydraulic pressure in testing been maintained for a longer period of time per pipe, for, as previously stated, air compressed will find its way through open or porous metal more rapidly than water compressed, but in view of the fact that all of the pipes were to be subjected to an air test subsequent to the hydraulic, both manufacturers depended more on developing leaks with the air than with the water. While it is true that both lots of pipe were laid for the purpose of carrying gas, the writer believes that in these days when the tendency is with all waterworks to operate as economically as possible and with as little loss of the commodity being dealt in, for the purpose of conserving the supplies already in use to their fullest extent before looking for new sources, or in considering the most economical way of conserving new sources of supply which are being considered, we should all consider seriously whether requiring a longer hydrostatic test, or in addition to the hydrostatic a pneumatic test of the pipe we purchase and lay, would not be good economy, even at the risk of having to pay slightly more for our material. In other words, whether the best is none too good, both in material and in laying, while the first cost may seem high will it not effect economies of both operation and commodity that will eventually prove considerable of a saving?

* Paper read before Central States Water Works Association by William R. Conrad, Burlington, N.J.

The Mechanical World states that aluminum may be etched by the following etching fluid; alcohol, 4 ounces; acetic acid, 6 ounces; antimony chloride, 4 ounces, and water, 40 ounces.

Don't fail to clean away all dirt and chips before screwing a chuck or faceplate on the lathe, and if the screw is dry, put on a few drops of oil.

A rust-proofing process for iron and steel, called Coslettising, consists in boiling the articles to be treated in a solution of 1 gallon of water, 4 ounces of phosphoric acid and 1 ounce of iron filings. By this means a black coating is produced on the iron or steel surface which protects it from atmospheric or other corrosive influences.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Foundry and Machine Shop.

MONTREAL.—Two blocks have been cleared for the erection of the Canadian Tube & Iron Company's works. This company is capitalized at $1,000,000. The intention is to have the first storey completed by early summer next year, and at once some machinery will be installed and manufacturing will start, while the rest of the building is being completed. When the whole works are in operation 400 or more men will be employed.

TORONTO. The Dominion Gasoline Engine Co. has been incorporated, with head office here. The capital is $75,000, and the provisional directors are A. N. Morine, R. H. Whiteway, M. Vetter, G. N. Shaver and G. G. Paulin.

WALKERVILLE.—The Gramm Motor-truck Co., recently incorporated for $100,000, are making complete motor trucks here. The plant of the Gramm Motor-truck Company of Canada comprises some 30,000 square feet of space, and the company owns additional adjacent land in the best locality in Walkerville, which will be called into requisition as conditions warrant. The President of the company is H. W. Acason, who is also Vice-President of the Walkerville Carriage Goods Co., and a member of the firm of Acason, Galusha & Rudd, makers of automobile tops and trimmings. John V. Carr, Vice-President; I. K. Webster, Secretary and Treasurer. F. H. Galusha, the general manager, is also president of the Walkerville Carriage Goods Co., and one of the firm of Acason, Galusha & Rudd.

MONTREAL—The National Acme Co. are installing Chapman double ball bearings in their new plant here, and also in the Crown Laundry.

TILLSONBURG, Ont.—Gaskell & Co., recently from England, have purchased the machine shop and foundry of H. F. McCrea. It is the intention of the new company to do general repairing, and also manufacture some general lines, when they become better acquainted with the requirements of the country. Mr. McCrea is retiring from active work. He has been a reader of Canadian Machinery for many years and has renewed his subscription, because he still wants to keep in touch with Canadian manufacturing interests.

SUDBURY, Ont.—The Sudbury Construction & Machine Co. are building an addition to their plant to be used as a foundry. This company manufactures mining machinery.

SAULT STE. MARIE.—The Northern Foundry & Machine Co. have completed their new blacksmith shop and foundry which replace those destroyed by fire some time ago. The plant has been fully equipped for the manufacture of boilers, etc.

PORT WILLIAM, Ont.—The various foundries and machine shops are busy with contracts for the C.P.R. and C.N.R. The Canadian Iron Corporation have 300 men employed and are rushing to their full capacity.

METEGHAN RIVER, N.S.—J. P. Robichaud is building a foundry and machine shop here.

SARNIA, Ont.—The J. B. Hicks Gas Engine Co. will establish a works here subject to the ratepayers authorizing a grant of $5,000 to the company.

MONTREAL, Que.—The Lightning Furnace Co., which has taken over the assets and business of the Compagnie de la Fournaise Limitee, will establish a foundry for the manufacture of furnaces and implements connected therewith.

HALIFAX, N.S.—At a meeting of the shareholders of the Silliker Car Co., held in Halifax, on December 6, it was decided to accept the amended offer of F. E. McCurdy to purchase the assets and business. The offer includes an undertaking to put $600,000 new capital in the business. The McCurdy interests will purchase $600,000 of the first preferred 7 per cent. stock.

HAMILTON, Ont.—The Dominion Power & Transmission Co. announced on Dec. 15 that it would spend $100,000 on new sub stations in this city, $220,000 on new works at Decew Falls Development plant and $30,000 on new cars for suburban traffic.

PORT ARTHUR, Ont.—The municipal authorities have now under consideration proposals for the establishing of new industries involving a capital outlay of $1,400,000. H. S. Jones, of Winnipeg proposes to build and operate car works. The plant is to cost $400,000. A free site of 15 acres is asked. A prominent American manufacturer is asking consideration for a project to put up automobile works there to cost $500,000. A foundry project in connection with the local blast furnace is also the subject of negotiation. Mr. Jones' plant would include in its output and operations machinery, cars, railway equipment and repairs.

LONDON, Ont.—It has been announced by the chairman of the Ontario Hydro-Electric Commission that the machine shops of the commission will be located in London, that being the central point in the transmission system.

ST. THOMAS, Ont.—A proposal to establish here an industry to employ 200 hands is being considered by the City Council. A fixed assessment for a number of years is asked for. Machinery is to be put in on a considerable scale, but no further particulars are given out.

WELLAND, Ont.—At a meeting held here this week it was decided by the directors of the Niagara Falls, Dunnville, and Welland Electric Railway Co., to expend $1,000,000 on railroad construction account. Car barns and machine shops are to be erected in Welland.

ROCHE POINT, B.C.—The Vancouver Dry Dock & Shipbuilding Company will construct a large dry dock here at a cost of $1,214,154. Work to be started within six months and finished by Dec. 1, 1912.

WOODSTOCK, N.B.—The machine shop in connection with Connell's Foundry was destroyed by fire on November 28. Insurance amounted to $21,000 on the entire plant, but the loss on the part destroyed exceeds that sum.

ST. BONIFACE, Man.—The council have closed an agreement with the Taggart Iron Works, of Winnipeg, by which the company will erect a large building here, as a branch industry. Building operations are to commence within five months.

CAMPBELLTON, N.B.—The Trans-Continental Railway Co. plans to erect larger buildings here, it is reported, at an estimated cost of $200,000. G. Grant, of Ottawa, is chief engineer.

LONDON, Ont.—It is understood that the McLaughlin Automobile Co. will erect a large building here.

TORONTO, Ont.—The Mexican Northwest Equipment Co., capitalized at $200,000, has received a federal charter. The company purpose manufacturing locomotives, cars, machinery and railway equipment of all kinds. Headquarters are to be in Toronto.

WELLAND, Ont.—The Hamilton Tube Co. ask for a fixed assessment of $1,500 for 10 years on a factory and plant they propose locating here.

ST. THOMAS, Ont.—F. Doty & Sons, of Goderich, will establish a shipbuilding yard at Port Stanley and have leased property for that purpose. Building operations are to commence at once. The firm will construct large tugs and have already received contracts for three such vessels.

TORONTO, Ont.—J. Wiss & Sons Co., New Jersey, have received a permit to manufacture shears, scissors, razors, knives, etc., in Ontario, the capital used not to exceed $40,000.

GALT, Ont.—The R. McDougall Co., manufacturers of machine tools and pumps, are enlarging their works.

CARLETON, N.B.—The Union Foundry Co. propose extending their plant.

RENFREW, Ont.—Mr. McLean, of Bryson, Que., is considering the establishment of a foundry and machine repair shop here. The proposed industry would handle lighter and more difficult work than is attempted by the ordinary foundry, the repair work being made a special feature.

MONTREAL, Que.—An annex to the boiler construction shop is being erected at the C.P.R. Angus shops here. The new building will be 160 by 116 ft. and is to be used for the construction and repair of locomotive tenders.

ST. CATHARINES, Ont.—The McKinnon Chain Co. are erecting a new plant here.

OTTAWA, Ont.—The Diamond Arrow Motor Car Co. and the Modern Machine Co. have decided to unite their concerns. The manufacturing will be done at the Modern Machine Co.'s works which will be much enlarged.

Electrical Notes.

PRINCE RUPERT, B.C.—As the result of passing an electric light by-law, the sum of $66,000 will be raised to pay for a civic lighting plant.

BROCKVILLE, Ont.—Nine municipalities were represented at a meeting held here on Dec. 14 to discuss the hydro-electric power question. It was decided to open negotiations with the commission for 5,300 h.p. to be divided among the different municipalities. Those represented were Iroquois, Morrisburg, Cardinal, Prescott, Lyn, Athens, Brockville, Kingston and Napanee.

PORT ARTHUR, Ont.—On November 24 the first power to come over the hydro-electric lines from Kakabeka Falls was delivered to this city. Only a temporary supply of 600 h. p. was given; the entire service commenced on December 15.

BELLEVILLE, Ont.—The Electric Power Co. is the name of a corporation that has control of several operating power companies in the Trent River district, and is proposing large extensions into the cities and towns of that region.

WINNIPEG, Man.—The Canadian Carbon Co., of Toronto, is establishing a branch factory in Winnipeg. The "Black Cap" battery will be the main article of production.

MONTREAL, Que.—A cable from London, Eng., on December 14 announced the formation there of the Montreal Tramways & Power Co., with a capital stock of $20,000,000. It is believed that the concern has been formed to take over the Montreal Street Railway.

STRATFORD, Ont.—Among other by-laws the ratepayers will be called to vote on one providing for the expenditure of $41,610 for electric light purposes.

ROLEAU, Sask.—The contract for the construction of an electric light plant to cost $60,000 will be let at an early date.

SHERBROOKE, Que.—The city has decided to develop power on the Magog river. The plans prepared call for the development of 2,600 h.p. at an estimated cost of $70,000. Tenders are to be asked for the purchase of the power which the city owns on the St. Francis at Westbury.

TORONTO, Ont.—The Western Central Railway Co., incorporated by the Ontario Legislature, is applying for a Federal charter. It is desired to extend the electric lines provincially authorized between Toronto and London to Windsor; also to establish a ferry connection from Windsor to Detroit.

Municipal.

ST. HYACINTHE, P.Q.—The Colonial Engineering Co., Montreal, have been awarded the complete lighting and pumping equipment for this city.

CHATHAM, Ont.—The ratepayers will vote on a by-law to provide a site of 7 acres at a price not exceeding $1,500 and a fixed low assessment for 10 years for the Western Bridge & Equipment Co. The company is to erect a $10,000 plant and spend an equal sum for equipment.

Calgary, Alta.—The construction of an incinerator is being discussed by the city. Estimated cost, $50,000.

SOURIS, Man.—Tenders for delivery during spring and summer of 1911 of water pipes, hydrants, gate valves, valve boxes, pig lead, oakum, standard vitrified sewer pipe, etc., will be received until February 1st, 1911.

PEMBROKE, Ont.—A by-law will be submitted to provide by way of loan the sum of $65,000 for the extension of the waterworks system here.

GUELPH, Ont.—A by-law to provide for the expenditure of $9,800 for waterworks improvements has been passed by the city council.

VANCOUVER, B.C.—$200,000 is the amount needed for new waterworks. A by-law authorizing the expenditure of this amount will be submitted to the ratepayers.

STAFFORD, Alta.—$15,000 is the amount this town proposes to spend on waterworks.

OAK BAY, B.C.—A by-law to authorize the expenditure of $60,000 will be voted on.

KINCARDINE, Ont.—The ratepayers will vote on a by-law to issue debentures for $7,000 for sewers and $2,500 for bridges.

Saw Mill and Planing Mill News.

SCOTSTOWN, Que.—The Emberton Lumber Co. have recently sold out all of their property at Scotstown, to the East Angus Co. The Emberton Co. have had possession of the property for nearly two years.

WINNIPEG, Man.—The Security Lumber Co. has been incorporated here with a capital of $500,000. John P. Jansen and Lorne J. Elliott are named as the incorporators.

FORT GEORGE, B.C.—Timber rights on 100 sections of land, principally in the Fort George district have been purchased by British capitalists from C. E. Mahon, of Vancouver and associates, for $1,500,000. It is said that there is over 2,000,000,000 feet of fine spruce, cedar and fir on the sections. Most of this lumber land is on the Willow river, 20 miles east of Fort George.

NELSON, B.C.—The shingle mill and box factory which will be erected by the Western Box & Shingle Mills, Limited, at Nelson, will be a frame building with iron roofing. It will be 36 feet by 48 feet and 2 storeys high. The estimated cost of the building is $1,000, and the machinery $4,000.

QUATSINO, B.C.—Arrangements have been made for the building of a saw mill at Quatsino, this winter. Behind this enterprise are James Guyer and Gustave Moerman, both residents of Quatsino. The mill men will start in a small way, catering principally to the home market.

FORT FRANCES, Ont.—The Shevlin-Clarke Lumber Co. propose erecting a large mill here and ask for a fixed assessment. This company is interested in the Rainy River Lumber Co. and the Shevlin-Mathieu Co.

BAY OF ISLANDS, Nfd.—The Humber Lumber and Pulp Co. is preparing to add to its works a very large pulp mill at Bay of Islands.

RIDGEWAY, Ont.—E. W. Near is erecting a two-storey addition, 28 by 56 ft., to his planing mill. On the ground floor will be offices and engine room. The upper floor will be used as a joiner shop.

VANCOUVER, B.C.—The Paterson Lumber Co. proposes to build manufacturing works to cost $250,000 to $300,000 in Vancouver, in connection with its existing business.

BRIGDEN, Ont.—The Dominion Cooperage plant and stave mill was completely destroyed by fire on November 30. Loss is $14,000, partly covered by insurance.

VICTORIA, B.C.—A new lumber mill, owned by the Vancouver Island Mining and Development Co., is in operation at Tyee Siding on the Esquimalt & Nanaimo Railway. The mill has a capacity of from 25,000 to 30,000 ft. per day.

NANAIMO, B.C.—Walter Marriott has purchased from Dickie, Van Norman, Haycroft and J. W. Vipond, of this city, their interests in the Quamichan Saw Mill Co. A joint stock company has been organized to take over the holdings.

WELLAND, Ont.—John E. Cutler, whose planing mill was recently destroyed by fire, is asking for a fixed assessment of $1,000 for 10 years, under which conditions he will erect a new mill.

ST. BONIFACE, Man.—The lumber mill of the Rat Portage Lumber Co. here, was burned on December 7. The loss amounted to $90,000 of which 75 per cent. was covered by insurance. The plant will be re-established at once, new machinery having been ordered.

RAINY RIVER, Ont.—The mill of the Rat Portage Lumber Co., which was burned some months ago during the forest fires, will be rebuilt early next spring.

MONTREAL, Que.—The sash and door factory owned by Phillipe Saumure was destroyed by fire on November 16.

HUMBERSTONE, Ont.—S. J. Dickinson's planing mill was totally destroyed by fire on November 25. The loss is $7,000, of which only $500 is covered by insurance.

ST. JOHN, N.B.—The cooperage plant of Taylor and White, here, was recently damaged by fire to the extent of $5,000. The plant was insured for $7,000.

ST. JOHN, N.B.—J. J. Gordon is completing a plant at Coldbrook, three miles from this city, for the manufacture of excelsior.

General Manufacturing.

BLENHEIM, Ont.—G. A. Fraser, of Thamesville, is considering the location of a canning factory here.

PETROLEA, Ont.—The 3-storey flour mill owned by W. W. Paing, of this town, was destroyed by fire on November 17. Total loss, $10,000.

GALT, Ont.—The C. Turnbull Co., woollen manufacturers, purchased two valuable pieces of property on King street, and will, it is stated, next year build a large extension.

HAMILTON, Ont.—In the spring the Diamond Flint Glass Co. will erect a large glass factory on a 10-acre site obtained for it in Hamilton by the Publicity Commisioner. When the new factory is completed the company will vacate its present premises in the city. It is also announced by the commissioner that the Egg-O Baking Powder Co. will establish works in Hamilton, and that the Robinson Box Mfg. Co., of Lowell, Mass., will do likewise. It is said that new factories of an aggregate value of $4,000,000 have been secured for Hamilton within the last twelvemonth.

MEDICINE HAT, Alta.—The Alberta Clay Products plant was formally opened on Nov. 26. Among the products of this plant are sewer pipe, fire roofing and all hollow wares of that class, every variety and grade of brick. Raw material can be handled to the amount of 600 tons per day.

FORT WILLIAM, Ont.—The Board of Trade has been in correspondence with a representative of Ely Bros., London, Eng., manufacturers of high-grade ammunition, who are favorable to locating a Canadian plant in this city.

MONTREAL, Que.—The Dominion Box and Package Co., which is capitalized at $700,000, will employ upward of 200 men. It is said to be a merger of several smaller companies, such as the Dominion Wire Bound Box Co. and the Montreal Box Co. It is also closely allied with Wm. Rutherford and Sons.

BOWMANVILLE, Ont.—The Goodyear Tire & Rubber Co., of Akron, Ohio, has purchased the business and plant of the Durham Rubber Co., of Bowmanville, Ont., and are now manufacturing a complete line of rubber products in Canada. From Van Bever, Vice-

Salesmanship Course Free
and a Liberal Salary

If a person wishes to take a course in Salesmanship he usually has to pay for it. But the MacLean Publishing Company pays for your course as well as offers you a very substantial salary if you write giving references and show that you are ambitious and capable of handling our circulation in your locality.

What could be more desirable for the young man, starting his business career, than to become connected with the MacLean Publishing Company, whose circulation organization is the strongest in the Dominion?

What could be more beneficial than to commence his career with an excellent training in salesmanship? The man who has had experience as a salesman is qualified for practically any business position.

The staff of the MacLean Publishing Company is being increased every week. The best men get the best positions. The best men are invariably those who are ambitious and who have been connected with the firm the longest.

Write at once for full particulars.

Building Notes.

ST. THOMAS, Ont.—The management of Alma College have decided to have a new wing erected, or a separate building at an approximate cost of $30,000.

SARNIA, Ont. The Board of Education have made a requisition to the council for the sum of $45,000 for the erection of a new school on the site of the present Lochiel street school.

PORT ARTHUR, Ont.—The city of Port Arthur has decided to erect a new collegiate institute at a cost of $125,000.

MONTREAL, Que.—The Canada Rubber Co. on December 19 obtained a permit for the erection of a factory to cost $250,000.

VANCOUVER, B.C.—The Vancouver Gas Co. is preparing to build a new plant on deep water frontage.

WELLAND, Ont.—New industrial buildings nearing completion are the Chipman-Holton Knitting Factory and the Peters Textile Factory. The new offices of the Ontario Iron & Steel Co. are also about finished.

New Companies.

The South Shore Gas Co., Montreal, Que., capital stock $100,000; to manufacture, buy and sell gas and electricity for lighting, heating and motive purposes. Montreal parties are named as incorporators.

National Hydro-Electric Co., Montreal, Que., capital stock $1,000,000; to carry on business of an electric light, heat and power company. Montreal parties are named as incorporators.

Canadian Electric Automatic Machines, Limited, Ottawa, Ont.; capital stock $225,000; to secure patent rights for automatic vending machines and to manufacture or deal in machinery and devices connected therewith. Ottawa parties incorporators.

The Granby Elastic Web Co., Granby, Que.; capital stock $50,000; to manufacture all kinds of rubber goods and webbing. G. H. Boivin, of Granby, is one of the incorporotors.

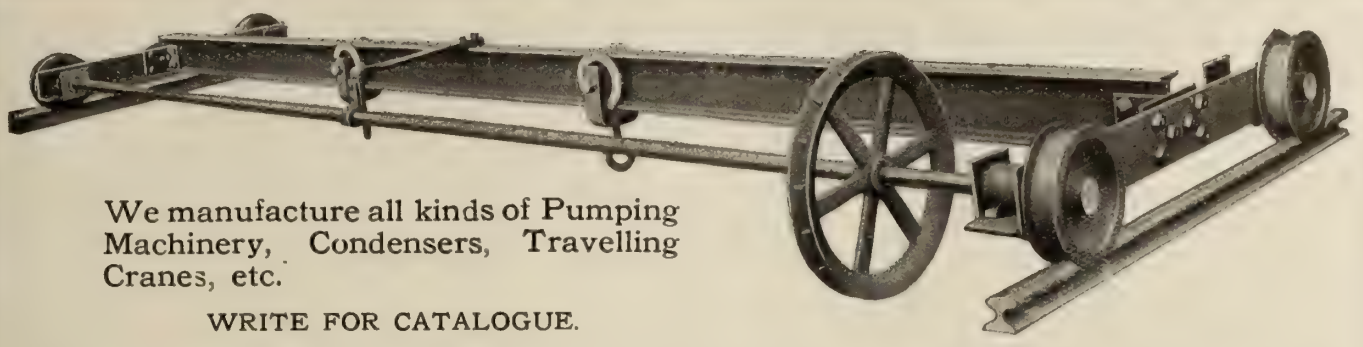
The Central Canada Power Co., Toronto, Ont.; capital $10,000,000; to carry on hydraulic and electrical power business in Canada. Members of a Toronto legal office are named as incorporators.

The Dominion Instantaneous Heater Co., Vancouver, B.C.; capital stock $100,000; to manufacture and purchase the selling rights of Gray's Instantaneous Heater. W. Francis, E. V. Chevalier, A. C. Brydon-Jack and E. B. Ross, of Vancouver, and A. P. Francis, of Victoria, are the incorporators.

Certificates of incorporation have been granted by the legislature of British Columbia to the Canadian Dry Battery Co., Electrical Advertising Co. and the International Lead & Iron Co.

The Loomis-Morden Cooperage Co., Trenton, Ont.; capital $30,000; to manufacture cooperage products, woodenware and lumber. Incorporators are Chester Loomis, H. B. Loomis and W. A. Morden.

Canadian Explosives, Limited, Montreal; capital $15,000,000; to manufacture all kinds of explosives, ammunition, firearms, etc. Incorporators nominally given as clerks in a Montreal law office. The Company has power to amalgamate other similar companies.



The Dryden Timber & Power Co., Dryden, Ont., have been incorporated with a capital of $3,000,000. The incorporators are: F. Singer, G. Waters and H. Hill, all of Toronto, Ont.

Trade Notes.

MONTREAL, Que.—John Watson & Son, architectural iron works, have been awarded the contract for the architectural iron work in connection with the large office building being erected by the Dominion Express Co. in this city. Contract runs to about $35,000.

BROWNING CRANES

How many mill owners have warded off the thought of buying a Locomotive Crane for handling of their logs and dimension timbers, thinking the equipment a LUXURY? Later you would be surprised at the great number of these same mill owners who, after seeing their smaller competitor install a "BROWNING," have investigated and found the outfit a NECESSITY and a money-saver instead.

"save-all" system as well as their pneumatic filtering system.

TORONTO, Ont.—The Chapman Double Ball Bearing Co. have recently received orders for their type of bearings for the addition to the Ideal Bedding Co. and for new plant of Mendelessohn Piano Co., Toronto; new forge shop, Verity Plow Co., Brantford; Amherst Boot & Shoe Co. and Canadian Car and Foundry Co., Amherst, N.S.

WOODSTOCK, Ont.—The Maximilian Pneumatic Tool Co. are installing machinery, an order having been placed with the A. R. Williams Co., Toronto, for machine tools amounting to $30,000. The company will soon be manufacturing a full line of riveting and Chipping hammers, sand rammers, air motors, air compressors, etc. J. R. Porter, Buffalo, is president of both the Canadian and U.S. Companies. The company is incorporated in Ontario for $100,000.

MONTREAL, Que.—The Canada Ford Co., owing to pressure of space have removed from their offices in the Canadian Express Building, and will hereafter occupy the entire building at 485 St. James Street (a few doors west of Inspector Street) Montreal, where they will carry a complete line of the products of the Brush Electrical Engineering Co., Loughborough, England, as well as ventilating fans and blowers, transmission material, machine tools and engineers' small tools and special machinery, etc.

TORONTO, Ont.—The Lancashire Dynamo & Motor Co., of Toronto, have been authorized by provincial legislation to engage in the manufacture of dynamos, motors and appurtenances. Heretofore the company has been but a distributing agency of the British company.

MONTREAL—Orders for transformers for the Hydro-Electric power sub-station at Port Credit, were secured by Allis-Chalmers-Bullock.

HAMILTON.—The Canadian Westinghouse Co. provided the switching equipment for the Hydro-Electric Power and sub-station at Port Credit

DETROIT.—The Northern Engineering Works are installing four Northern cranes ranging from 5 to 15 tons capacity in the plant of the Kewanee Boiler Co., Kewanee, Ill.

TORONTO.—Announcement is made of an important change in the management of the Goldschmidt Thermit Co., of 90 West Street, New York, and who have a branch here. Commencing October 1st, E. Stutz, vice-president and general manager, retires from the direction of the company, which passes under the management of William C. Cuntz. Mr. Cuntz brings to his position a thorough knowledge of the steel business and a wide acquaintance with the railway and street railway officials of the country, having been connected for eighteen years with the Pennsylvania Steel Co.

HAMILTON.—The Smart-Turner Machine Co., 191 Barton St., East, report the following orders for their pumps of which they make several types: Deloro Mining & Reduction Co., Dolero, Ont.; Thos. A. Ivey & Sons, Port Dover; Gunns, Ltd., Toronto; Beardmore & Co., Acton, Ont.; Royal Crown Soap Co., Vancouver; Dresden Canning Co., Dresden, Ont.; S. L. Snively, Nelles Corners, Ont.; Peoples' Ry., Berlin; General Hospital, Toronto, and A. Dobson, Beaverton. A traveling crane is being supplied to the C.P.R., Winnipeg, and one to the Ouiatchouan Falls Paper Co., Ouiatchouan, P.Q. The Oliver Chilled Plow Works have placed orders for two tumbling barrels with the Smart-Turner Machine Co.

Western Steel & Iron Co.

The Western Steel & Iron Co., Winnipeg, has become the successor to the Western Iron Works, of that city, with considerably increased resources. It proposes to manufacture ornamental and architectural iron work, forgings, castings, railroad and contractors' materials and specialties on an extended basis. The officers of the company are: President, C. M. Simpson; vice-president, Alex. Simmers; manager and secretary-treasurer, H. R. Eade.

New Machinery Agency, Montreal.

Foss & Fuller is the name of a new machinery house who have opened at 329 St. James Street, Montreal, comprising Geo. F. Foss, who was for four years a traveling salesman for Williams & Wilson, Montreal, and M. A. Fuller, who was connected with the Canadian Rand Drill Co., of Sherbrooke. They have secured the agency of some prominent Amer-

ESTABLISH A MODERN TAX-FREE ALCOHOL DISTILLERY
We have a Good Proposition for Motor Mfrs.

Having exported our Stills in large amounts for many years, and already having several far Eastern agencies we are now open to establish additional agencies and invite correspondence to that end, looking after our old customers and prospective buyers by special successful demonstrative methods for making Alcohol, Apple Jack, Aguardiente, Mescal, Teguila, Peach Brandy, Whiskey, etc. Most modern and simple. All sizes, 5 to 500 gallons daily capacity distilling apparatus.
ARE YOU LOOKING FOR information relating to INDUSTRIAL or DENATURED ALCOHOL DISTILLING APPARATUS and the amazing possibilities of the utilization of waste farm products and wood waste by superheated steam distillation, the distilling apparatus as used by us; the principle involved, also the methods of chemical control and disposal of the product and by-products? We will gladly say to you:
Denatured Alcohol to-day is of the greatest untold benefit to the American motor people. It opens an absolutely new field for investment for progressive paper pulp and chemical fibre mills, paint, varnish, soap and candle makers, gardeners, farms and garbage plants, saw-mills, lumbermen and canneries. The Automobiles and the Navies of the world clamor for this new tax-free cheaper industrial alcohol. May we expect some encouragement from the more patrotic pioneers for this new American Industry? The field is new and profitable, and you can practically have the business your own way by starting now. We are makers of an apparatus for the production of this denatured or industrial alcohol; we build and install plants—large or small. The initial cost of a plant is small; the financial risk—if any—is trifling. The equipment is such that it can be added to at any time without disturbing the original installation. Address

ican manufacturers, amongst others:—Schumacher & Boye, Lathes, Cincinnati; Geo. A. Gray, Planers, Cincinnati; Mueller Machine Tool Co., Radial Drills, Cincinnati; The J. T. Slocombe's line of Micrometers and the O.K. Tool Holders.

A. R. Williams Co. in New Brunswick.

The A. R. Williams Machinery Co. have been incorporated in New Brunswick and will open up a branch in St. John, N.B. The incorporators are A. R. Williams, Thomas A. Hollinrake, Toronto; M. W. Doherty, St. John; F. W. Kischel and Robert Kerr, Brantford. The capital is $99,000, of which $50,000 is paid up. The St. John manager is M. W. Doherty. A large building in St. John has been purchased. Stocks of machine tools, wood-working machinery, boilers, engines, saw mill machinery, belting, etc., will be carried.

Toronto Agency Northern Cranes.

A Toronto office of the Northern Engineering Co., Detroit, and their Canadian branch, the Advance Machine Works, Walkerville, manufacturers of Northern Cranes, has been opened up at room 623 Traders Bank Bldg. The office is in charge of W. P. Robinson, who will also represent the Canadian Crocker-Wheeler Co., manufacturers of electrical machinery; American Electric Fuse Co., Muskegon Heights, Mich., manufacturers of controllers, starters, etc., and Hooven, Owen, Rentschler Co., Hamilton, Ohio., manufacturers of Hamilton Corliss engines.

Manufactures Dies in Montreal.

An item appeared in the November issue of Canadian Machinery with reference to the demand on the part of many small manufacturers for dies for punching brass, metal, etc. Ernest Scott, 145 Bleury Street, Montreal, writes us that he is a manufacturer of all kinds of dies of this nature and in a position to submit prices on all work of this kind.

Montreal Branch, Thos. Firth & Sons.

Thos. Firth & Sons, of Sheffield, England, have opened up a branch office and warehouse at 507 St. Paul Street, Montreal, where they intend carrying stock of their tool steels, etc. The business is under the management of J. A. Sherwood, formerly of Pittsburg, who has had a long and sucessful experience with the company.

Massey-Harris Co. Enlarging.

The Massey-Harris Co. have bought out the works of the Johnston Harvester Co., Batavia, N.Y. The Massey-Harris Co. are enlarging their Toronto and Brantford plants, having secured additional property adjacent to these plants. The buying of a plant in the United States is to assist in taking care of their foreign trade.

Pumps for N.T.R. Shops.

The John McDougall Caledonia Iron Works Co., Montreal, are furnishing a number of pumps for the N.T.R. shops at Transcona, near Winnipeg. These consist of two 8-in. single stage horizontal turbine pumps, with extended bases. Each of these pumps is direct connected on the same base with an 18 in. six-stage 70 h.p. horizontal Kerr Steam Turbine, running at 1,500 r.p.m. The capacity of each of these machines is 1,200 U.S. gallons per minute when operating against total head of 150 feet. The pumps were manufactured in Montreal, and the turbines were made by the Kerr Turbine Co., Wellsville, N.Y.

Two 14x10¼x10 Blake horizontal duplex piston pattern boiler feed pumps, mounted on cast iron bedplates. Each of these pumps will have capacity of 200 U.S. gallons per minute and used for supplying boilers operating under 150 lbs. steam pressure.

Two 6x4¼x3x36 Blake vertical Artesian Well Pumps. Each of these machines are used to draw water from 6 in. diameter Artesian wells and deliver to a high level tank at an elevation of 120 ft. above ground level, and will have capacity of 40 U.S. gallons per minute when operating under the above conditions. These latter pumps are manufactured by the George F. Blake Mfg. Co., East Cambridge, Mass.

One 26-in. Vertical Centrifugal Pump, direct connected to one 350 h.p., 450 r.p.m., 3 phase, 60 cycle, 550 volt, type "F" Motor, complete with cast iron base and thrust bearing to take care of the weight of the rotor only. This pump is designed to have capacity of 16,000 Imperial gallons per minute against total head of 48 feet, and will have an efficiency of 70 per cent. when operating under the above conditions and running at a speed of 436 r.p.m. The motor will be controlled by Cutler-Hammer 350 h.p. automatic motor starter, complete with ball, float, chain and switch. It will also be supplied with hand-operating controller and resistance. There will also be supplied in connection with this

outfit a motor panel to mount the following instruments:—

One 400 amp. 3 pole single throw automatic oil switch.
One 500 amp. Weston Ammeter.
One 600 volt Weston Voltmeter.

This panel will be made of Blue Vermont Marble, complete with frame work and connections.

One 8-inch Centrifugal Sewage Pump, direct connected to 30 h.p. motor with Cutler-Hammer starting controller and resistance, complete with float switch and float ball and chain. This outfit will have capacity of 2,000 Imperial gals. per minute when operating against total head of 15 ft. The pump will have an efficiency of 56 per cent. when operating at a speed of 436 r.p.m. This outfit will also have a motor panel with the following instruments mounted on same:—

One 50 amp. type "E" automatic oil switch.
One 60 amp. Weston Ammeter.
One 600 volt Weston Voltmeter.
All complete with frame work, etc.

The pumps will be manufactured in the John McDougall Caledonia Iron Works at Montreal and the Allis-Chalmers-Bullock, Montreal, are supplying the electrical apparatus.

All the centrifugal pumps will be designed under the supervision of Consulting Engineer, William Clinton Brown, formerly chief engineer of Henry R. Worthington, New York.

$7,000,000 of Equipment Ordered by C.P.R.

Over $7,000,000 worth of new cars and train equipment has been ordered by the C.P.R., all to be delivered by next summer. Two thousand refrigerator, coal, box, and other class of freight cars, and 200 coaches for passenger train equipment, including baggage, express, sleeping, dining, parlor and observation cars are at present under construction at the company's Angus shops, and, besides these, orders have been placed with other firms for 2,000 steel frame box cars of 80,000 lbs. capacity, to cost over two million dollars. Five hundred stock cars and 800 flat cars have also been ordered from outside. Orders for seventy-five heavy locomotives have also been placed in Canada, at the Angus shops, Kingston, and Montreal Locomotive Works.

The policy of the Canadian Pacific Railway indicates that they are planning to cope with any business that may be offered, with ample equipment built by Canadian workmen. They have never lacked confidence in the rapidly growing trade of Canada and the great transportation possibilities of the country's future.

CATALOGUES.

Steel and Wood Pulleys—The Oneida Steel Pulley Co., Oneida, New York, have issued a 48-page, 6x9 ins., illustrated catalogue of steel and wood pulleys and other specialties.

Calendar.—J. R. Baxter, 102 St. Antoine St., Montreal, have published an attractive calendar for 1911, which they are sending to their customers and friends.

Graphite Products for Railroads.—A new booklet has just been issued by the Joseph Dixon Crucible Company, of Jersey City, N.J., under the above title. This, as its name implies, covers the Dixon line of products that the widely used in railroad service.

The object of the book is to bring under one cover all the various products in the Dixon line that are of interest to the various mechanical departments of railroads. These include various graphite lubricants, protective paint, crucibles, facings, etc., all of which have been found by actual service to give satisfactory results.

The booklet runs to 40 pages, and is quite attractively illustrated by means of photographs showing different views of railroad stations and yards, different types of locomotives, stretches of track, signals, bridges, etc. If you are interested in the use of any graphite products about the railroad, you should write for copy of this booklet, which will be sent free to those desiring it.

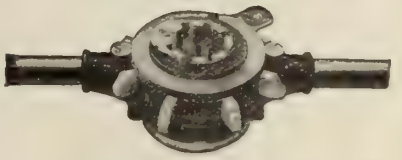
specifications are given, and a number of tables of useful information completes the catalogue. The customary system of marginal numbers has been retained and both numerical and alphabetical indices render it a simple matter to locate any tool quickly.

Screw Machines. The National-Acme Mfg. Co., Cleveland, Ohio. Calendar. Size 12x15 in. Each of the 12 leaves in addition to giving the calendar for one month contains an illustration either of a screw machine or some of its products. Among these are the multiple spindle screw machine and some products of the screw machine milling attachment.

Handling Coal.—Bulletin No. 42 from the press of the Jeffrey Mfg. Co., Columbus, O., is entitled "Coal Handling and Mine Equipment," and is a 48-page catalogue descriptive of this line of machinery. This book, which is larger than the usual Jeffrey publication, describes the Jeffrey Coal Tipple, illustrating a number of recent installations. In addition, numerous illustrations from their minor pamphlets, describing other coal handling machinery, giving the pamphlet number where more detailed information is to be had. It serves as a review book of their coal handling machinery.

Celfor Tools.—Catalogue No. 10, of the Celfor Tool Co., Railway Exchange, Chicago, Ill., a handsome 30-page booklet, describing their line of drills, chucks, shanks, reamers, 3-lipped drills, sockets for reamers and 3-lipped drills, and Rich flat drills and chucks. Besides describing and listing their respective prices, in a comprehensive manner much useful information concerning drill and reamer speeds, etc., and additional tables are given. The Celfor drills and reamers are made from flat high speed steel bars, twisted to shape, and in catalogue they are illustrated in operation.

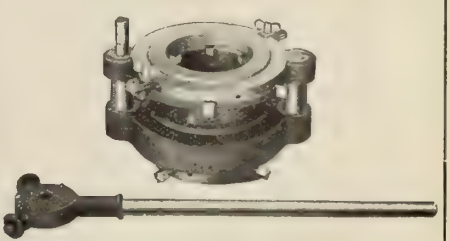


Standard Automobile Gauges.—This line as manufactured by the Industrial Instrument Co., Foxboro, Mass., is described in their bulletin No. 36, a 4-page folder. As well as briefly describing the gauge and its features, its varied uses on an automobile are given, showing that it would be to the advantage of automobile owners to have them.

Multiple Drilling Machines.—Section B of the 1910 series of catalogues, entitled Modern Machine Tools, issued from Webster & Bennett, Ltd., Coventry, England, is a 32-page booklet, descriptive of this line of tools, and gives a large variety of the different multiple drilling machines that they manufacture, enumerating the salient features of each as well as their size, weights, etc. Among the machines are various types of drilling machines, combined drilling and boring machines, combined drilling, boring and tapping machines and sensitive drilling machines.

Motors.—Continuous current protected and ventilated motors are dealt with in the 4-page leaflet No. 9, from S. W. Broadbent, Ltd., Huddersfield, England. The principal parts of the machine are briefly described, and the original features dwelt upon. In addition, is a general description of the machine, and a list, which includes prices, and data concerning a number of different sized machines.

Series Arc Lighting System.—With Cooper Hewitt Rectifier. This is the subject of Circular No. 1155, of the Canadian Westinghouse Co., Ltd., Hamilton, which is a 32-page booklet descriptive of this system of lighting. The system in detail is fully explained,



ONE MAN
can cut threads on 6-in. pipe with a

with all the auxiliary apparatus, making in all a very instructive booklet on lighting.

Radial Drills.—The 2½, 3 and 3½ foot arm, simple type radial drill, manufactured by the Mueller Machine Tool Co., Cincinnati, O., are described on leaflets just issued by that company. They are machines which they are making in conjunction with their standard radial drills. Special reference is given to the general dimensions, and also the salient features pertaining to the column, arm, head, tapping mechanism, feed, spindle, depth gauge and automatic trip, base, plain square box table, and motor. Excellent cuts of the drills with arrowed description are given in the pamphlets.

Hack Saw Blades.—Catalogue No. 16 of the Diamond Saw and Stamping Works, Buffalo, N.Y., is a 16-page booklet, attractively gotten up. In it are described and listed the various lines of "Sterling" hack saw blades, frames, power machines, etc. The advantages of the different lines are set forth, and the kinds best suited to the various lines of work are given. An accompanying 4-page leaflet describes their 3 sizes of high speed power hack saw machines, and includes the results of a production test.

Small Tools and Machinery.—The catalogue of the Hamilton Tool Co., Ltd., Hamilton, Ont., describes their line of small tools and machinery. Among the articles enumerated are Beaver drills and collets, ball bearings, milling cutters, reamers, slotting saws, sensitive drill, and bench drill. In addition are a list of letters of commendation from satisfied patrons. The articles shown are listed in a very convenient manner for ready reference. Much useful matter is contained, as the Beaver collet, especially, is described in considerable detail.

Blowers.—The American Blower Co., Detroit, have issued bulletin No. 286, entitled "Blower Equipment for the Modern Foundry." An excellent article on heating and ventilating the foundry, is given, dealing with that subject at some length, showing how their blowers can be used to advantage. In addition are articles or blowing equipment, exhaust systems, ABC forge blower, ventilating apparatus, mechanical draft apparatus for steam boilers, and ABC vertical enclosed self-oiling steam engines. An additional article at the back of the book gives some interesting figures on comparisons of isolated lighting plant cost with central station service.

Money and Labor Savers.—Is the title of a large 12 double page catalogue of neat design, issued by Walter MacLeod & Co., East Pearl St., Cincinnati, O. As the cover states, it is for the busy man who has not time to wade through a large catalogue, and for that reason is made very concise, containing no reading matter whatever, only titled illustrations, of which there are several dozen, of a good size. Fuller catalogues of the various machines are also to be had. Among the articles illustrated are the Buckeye lead and babbitt meltin furnaces, heater for foundry, heaters of general types, carbide lights, kerosene lights, locomotive and car tire heaters, weed burners, oil furnaces and forges, water softening plants, paint and whitewash sprayers, and sand blasts. For ready reference, it is extremely handy.

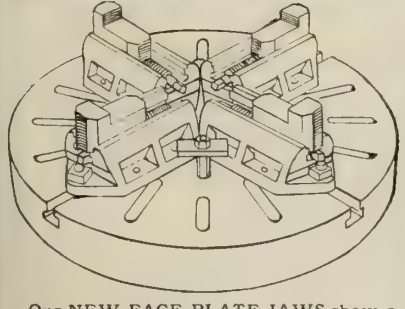
The Jones Improved Stamping
PRESS GUARD

This Guard is very simple, yet absolutely positive in its action, as the operator cannot trip the press while his fingers are in the danger zone. Also the press cannot repeat unless the Guard is down in front of dies, and then the operator cannot have his fingers in at the same time. The gate should be set so that it is down on base of die or bed of press when the latch of press releases. Then when the operator releases the treadle the gate will rise from 3 to 7 inches, according to requirements, leaving the front open to take out and put in work.

This Guard can be set so fine that anything 1-16 inch thick under the Guard gate will prevent the press from operating. Thus you can see it is utterly impossible for an operator to have his fingers between the dies and trip the machine at the same time.

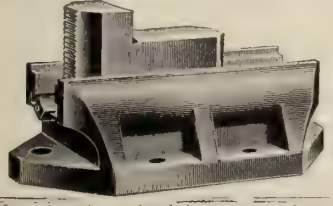
Is not in the operator's way and does not interfere with the output of press; works on all kinds of presses, back-geared, large or small.

Note the rigid connection between Treadle, Guard and Latch.



These Guards are already installed in a number of large manufacturing plants and are giving every satisfaction.

We also manufacture guards for woodworking machines.



Write us for circular matter.

Nothing Ever Like It

Our NEW FACE PLATE JAWS show a distinctly improved mechanical design---a quality for which this company is becoming known.

Note that the ends of the jaws are beveled to an angle of 45 degrees so that they will fit closely together when brought to the centre. When holding small work they can be run clear to the centre (as shown in cut) and held by clamp bolts entering the side pockets. Made in sizes from 4-in. to 14-in.

LET US FIGURE ON YOUR REQUIREMENTS

Power Talk No. 2—

Savings Actually Demonstrated

Read the following extracts from letters of leading Canadian firms:—

"Undoubtedly great power savers."—Cudahy Packing Co., Toronto.

"They are making us a saving of over 24 per cent."—Reliance Knitting Co., Ltd., Toronto.

"Saving of power has surprised us. Before your bearings were installed, our engine was up to her capacity, and we were unable to get sufficient power to light our plant. Since installing, have sufficient power for factory purposes and lighting, and have sufficient dry steam for heating a small addition to the factory. Our saving is about 20 h.p."—Adams Bros. Harness & Mfg. Co., Ltd., Toronto.

"After installing your Ball Bearings, we experienced not only a great saving of power, but all the previous trouble we had relative of lubricating and keeping our shafting in condition was eliminated. They have paid for themselves in the saving of power and also in saving of attention and care. The bearings have been on our shafts for a year and a half."—The William Davies Co., Ltd., Toronto.

"Have been using your double ball bearings for the past two years; find them a great power saver. By actual test we find they have saved us 25 per cent."—Puritan Knitting Mills, Ltd., Toronto.

"Over four years ago we equipped our shafting throughout with your bearings. Since that time we have installed more. The saving is what you claim, generally from 20 per cent. to 25 per cent."—The Cowan Co., Ltd., Toronto.

"Shafting installed some eighteen months ago has given far more satisfaction than even our most sanguine expectations. We have made a saving of from 20 per cent. to 25 per cent. Will further equip with your bearings."—The Canadian Locomotive Co., Ltd., Kingston.

"Running large portions of our machinery with these bearings for four years. Have effected a great saving in power."—The Flavelle Milling Co., Ltd., Lindsay.

"Have over 300 of your Ball Bearing Boxes in use in our factory. Have given us entire satisfaction in every respect. We ran friction tests in comparison with the ordinary babbitt boxes, and found the Ball Bearing Boxes greatly reduced the friction load."—T. H. Schwitzer, Factory Engineer, the Northern Electric & Mfg. Co., Ltd., Montreal.

"Five years ago we installed Chapman Double Ball Bearings throughout plant No. 2. Since that time we have been adding short lines of shafting and bearings, and we finally decided to replace all old friction shafting with ball bearings. This has been accomplished with a resulting saving of about 50 per cent. in power."—Taylor-Forbes Co., Ltd., Guelph.

Booklet, containing copies of letters from which the above extracts are taken, sent on request.

NOW THE THIRD CITY IN CANADA

WINNIPEG

MANITOBA

The Supply City of Western Canada

Offers greater combined advantages to manufacturers and capitalists than any city in Canada. The remarkable development of this great central market is creating an unprecedented demand for home industries.

Winnipeg Wants These Manufacturers

and offers cheap power, cheap sites, low taxation, varied raw materials, the best of labor conditions, unexcelled railway facilities, and the earnest support of a community that recognizes the importance of its industries. Over a billion dollars produced by the farms of Western Canada in the past five years, and this with only eight per cent. of the available land under cultivation. Consider what this development makes possible for the home manufacturer.

YOUR OPPORTUNITY

GET CLOSE TO THIS MARKET

Special openings for manufacturing farm and agricultural implements, including gas and steam tractors; paper and strawboard mills; men's clothing, ladies' ready-to-wear goods, foodstuffs, starch factory, boots and shoes, felt wear, metal goods, wire nail factory, hardware specialties, flax and jute works, beet sugar factory, elevator machinery, electrical fixtures and appliances of all kinds, automobiles and commercial motor carriages, home and office furniture, leather goods, cereal foods, dairy supplies, building materials, stoves, ranges, furnaces and heating plants, and twenty-five other smaller lines.

Special reports prepared and mailed free of charge on the manufacturing possibilities of any of these lines of industries, by addressing **CHAS. F. ROLAND**, Commissioner of Industries, Winnipeg, Canada.

A Double Economy

Carborundum Grinding Wheels are not only the fastest cutting but also the longest lasting grinding wheels on earth. For instance:

An Indianapolis concern is using Carborundum Wheels in grinding cast iron piston rings. Each wheel turns out 450 to 500 rings an hour, removing .010 inches stock. And yet, notwithstanding the speed at which the wheels cut, the michrometer shows that 50 rings are ground before there is any perceptible wheel loss. Result —A Double Economy.

We will be glad to show you what Carborundum is doing in other lines of grinding—if you will write.

Don't fail to mention "Can adian Machinery" in writing to advertisers.

Machinery Wanted and For Sale

AGENT WANTED.

AGENT WANTED by old established London firm for the sale of Electric Passenger and Goods Lifts in Canada. Must have recognised business and good connection. Box 20, CANADIAN MACHINERY, 88 Fleet St., London, Eng. (11)

FOR SALE.

FOR SALE Waterloo Iron Works, in town of Waterloo, Quebec, in centre of the Eastern Townships. Plant comprises foundry, machine shop, stove mounting and wood shops, and boilerhouse brick buildings, galvanized iron roofs—all in good repair. Canadian Pacific and Central Vermont Railways run through the town—works situated only a few rods from former. Splendid opportunity for any who wish to engage in manufacturing. Terms reasonable. Address, Waterloo Iron Works, Waterloo, Quebec. (8)

FOR SALE.—Jobbing Machine Shop and Foundry Business, located in Western New York, established over 50 years. Has large and very profitable trade. 75% of the capital stock can be bought for $85,000.00, worth $100,000.00 at least. Fine equipment of tools and well organized working force. This is not a debt encumbered concern that needs financing, no extra capital required for operating, but a going concern that owners want to sell on account of other interests preventing personal attention. For further particulars, address R. W. Gardner, 821 Railway Exchange Building, Chicago, Ill. (10)

FOR SALE—Belting, pipe rails, pulleys, shafting, hangers, chains, all sizes, new and used, half-price. Also cotton waste and wipers. Imperial Waste and Metal Co., Queen St., Montreal. (11-11)

MACHINERY FOR SALE.

FOR SALE—48" x 12' Iron Planer. Sellers pattern. Good condition. Gilson Manufacturing Co., Limited, Guelph, Ont. (1)

FOR SALE—One single hoisting friction engine, with extra large boiler on wheels, in perfect order 12 horse power. Apply William Welsh, 77 Jurors Street, Montreal. (12)

MARINE GASOLINE MOTORS of unexcelled quality; jump spark type; two to eighteen horse-power; pleased to show our motors; send for new catalogue. Midland Engine Works Company, Midland, Ont. (1-11)

FOR SALE—2 new 34" square x 10 ft. Planers, double heads. 2 second-hand 40" x 46" x 10 ft. Planers, double heads, rebuilt, practically good as new. Immediate delivery. NEW HAVEN MFG. CO., New Haven, Conn. (7)

FOR SALE—A complete set of patterns and equipment for the manufacture of an improved line of iron toys, such as trains, hose carts, hook and ladders, engines, pistols, banks, stoves, etc. An established demand for this particular line of toys. Everything necessary for the successful manufacturing of same. Very fine proposition for anyone interested. Reason for discontinuing manufacture lack of factory room on account of heavy lines of other materials. Address Box 107, CANADIAN MACHINERY, Toronto.

THE PEMBROKE ELECTRIC LIGHT CO., LTD., have the following Machinery for sale, which will be sold separately, or as a unit.

This Plant comprises the complete outfit of their steam station, and is in first class running order.

2 return boilers—14' x 66" (tubular)
1 " " —12' x 54" "
1 Wheelock Engine—15" x 34", speed 95 R.P.M.
1 " Tandem Compound Engine—9" x 24" & 17" x 24"—speed 95 R.P.M.
1 Generator, 3 phase, 225 K.W., 60 cycles, 2200 volts, 450 revolutions.
1 40 amp. Exciter.
1 Marble Panel with Instruments.
1 Jet Condenser
1 Duplex Steam Pump.
50 feet 4" shaft with pulleys, including 2 friction pulleys
1 double leather belt—50' x 30"
1 " " " —73' x 22"
1 " " " 70' x 16"

PEMBROKE ELECTRIC LIGHT CO., LTD.
Pembroke, Ontario (tf)

MACHINERY WANTED.

ONE PRESS, foot power preferred. Also ¼ or ½ h.p. alt. current motor, 104 volt, 60 cycle. E. D. Smith, Magog, Que.

FOR LEASE.

FOR LEASE—Brass and Aluminum Foundry in Indianapolis, Indiana. Thoroughly modern in equipment and appliances. Did a business last year of nearly $200.000. Second largest automobile centre in the United States, over thirty automobile factories in city and vicinity. Present owner engaged in other business requiring his time. Address Frank E. Janes, care F. E. Janes Coal and Grain Co. Indianapolis, Ind. (6)

BUSINESS CHANCES.

WANTED—A small Machine Shop to rent, with option of buying. Box 91, CANADIAN MACHINERY, Toronto (11)

POSITIONS WANTED.

ENGINEER, power gas, take charge of complete plant, engines and producers. Experience erecting, testing and running; undertake all repairs; first class electrical experience, sound technical knowledge, excellent references; prefer Ontario or British Columbia. R. BELL, 128 14th St., Brandon, Man.

FOREMAN Moulder is desirous of a change. First-class moulder; well up in modern methods of foundry practice; exceptional experience; good references. Box 88, CANADIAN MACHINERY, Toronto. (9)

PRACTICAL MACHINIST desires position as general foreman or superintendent. Good systematizer, with executive ability. Can handle all grades of labor. Box 106, CANADIAN MACHINERY, Toronto. (6)

PATTERN MAKER—Young energetic pattern maker, fourteen years' experience, two as foreman, desires position as foreman. Good executive ability and thorough knowledge of drawing and foundry practice. Address Box 90, CANADIAN MACHINERY, Toronto (11)

SITUATIONS VACANT.

WANTED—Mechanical Draughtsman on jig and tool design and general mechanical shop equipment. Give particulars of previous experience and salary expected. Box 89, CANADIAN MACHINERY, Toronto (11)

TRAVELER WANTED.

ENGLISH FIRM of high class machine tool makers requires services Canadian representative to work on commission. Apply Box No. 27, CANADIAN MACHINERY, 88 Fleet St., London, England. (8)

PATENTS.

THE PROPRIETOR of the Canadian Patents, Nos. 119683 and 114649, "Improvements in Multiple Cylinder, Internal Combustion Engines," and "Improvements in Reversible Valve-Gear for Interna Combustion Engines, Steam Engines, Air Compresors and the like," is desirous of entering into arrangements by way of license or otherwise for practically working the patents. For particulars apply KLAUSER & CO., 9 Friedrich St., Berlin, Germany. (6)

MISCELLANEOUS.

A BOOK-KEEPING STAFF IN ITSELF—doing the work with machine-precision and accuracy, the National Cash Register. Write us for demonstration literature. National Cash Register Co., 285 Yonge St., Toronto.

AT LAST—A really practical pencil sharpener. The "Spiro" sharpener built on a new principle, positively does not break the lead. Ten blades. Sharpener lasts lifetime. Every pencil user needs one. Pencil sharp in a second. Ask your stationer or write us direct. A. R. MacDougall & Co., Canadian Agents, Toronto.

ACCURATE COST KEEPING IS EASY if you have a Dey Cost Keeper. It automatically records actual time spent on each operation down to the decimal fraction of an hour. Several operations of jobs can be recorded on one card. For small firms we recommend this as an excellent combination—employees' time register and cost keeper. Whether you employ a few or hundreds of hands, we can supply you with a machine suited to your requirements. Write for catalog. International Time Recording Company of Canada, Ltd. Office and factory, 29 Alice Street, Toronto.

BUSINESS MEN, professional men, merchants and church workers, find innumerable uses for Fulton Sign and Price Markers. The Fulton Rubber Type Company of Elizabeth, N.J., are makers of Ink Pads, Daters and Business Outfits of high quality. Sold by all stationers. A. R. MacDougall & Co., Toronto, Canadian Agents.

COPELAND-CHATTERSON SYSTEMS—Short, simple. Adapted to all classes of business. Copeland-Chatterson-Crain, Ltd., Toronto and Ottawa. (tf)

DOUBLE YOUR FLOOR SPACE. An Otis-Fensom hand-power elevator will double your floor space, enable you to use that upper floor either as stock room or as extra selling space, at the same time increasing space on your ground floor. Costs only $70. Write for catalogue "B." The Otis-Fensom Elevator Co., Traders Bank Building, Toronto. (tf)

DURING 1910 the MONARCH displaced hundreds of Typewriters of all makes. In 1911 we anticipate a still greater demand. We have cut down the allowance on these second-hand machines and consequently can sell them cheaper to you. They are carefully rebuilt and are guaranteed to give satisfaction or your money back. If you want a good, strong, clean working Typewriter at a mere fraction of the original cost, write us for catalogue. THE MONARCH TYPEWRITER CO., Ltd, 46 Adelaide Street West, Toronto, Ont.

EGRY business systems are devised to suit every department of every business. They are labor and time savers. Produce results up to the requirements of merchants and manufacturers. Inquire from our nearest office. Egry Register Co., Dayton, Ohio; 123 Bay St., Toronto; 258½ Portage Ave, Winnipeg; 308 Richards St., Vancouver.

ELLIOTT-FISHER STANDARD WRITING-ADDING MACHINES make toil easier. Elliot, Fisher, Limited, Room 314, Stair Building-Toronto.

The advertiser would like to know where you saw his advertisement—tell him.

MISCELLANEOUS.

COUNTER CHECK BOOKS — Write us to-day for samples. We are manufacturers of the famous SURETY NON-SMUT duplicating and triplicating Counter Check Books, and Single Carbon Pads in all varieties. Dominion Register Co., Ltd., Toronto.

ELIMINATE FIRE RISK, save insurance, reduce maintenance costs and save money on your actual building work by using the Kahn System of Fireproof Construction. Used in many of the largest business premises on this continent. Write for catalogue. Trussed Concrete Steel Company of Canada, Limited, Walker Rd., Walkerville, Ont.

GET THE BUSINESS—Increase your sales—Use Multigraph typewritten letters. The Multigraph does absolutely every form of printing. Saves you 25 p.c. to 75 p.c. of your printing bill. Multigraph your office forms, letterheads, circular letters. Write us. American Multigraph Sales Co., Ltd., 129 Bay Street. Toronto.

IF YOU have been afflicted with one of those fountain pens that won't write when you want it to, or leaks when you don't want it to, give it away to one of your poor relations and buy a Moore Non-Leakable Fountain Pen and you will be happy. Consult your stationer. W. J. Gage & Co., Toronto, sole agents for Canada.

INDISPENSABLE in office, store, home—Canadian Almanac, 1911—a National Directory. Complete classified information on every subject of Dominion interest. Full Postage, Customs, Banking, Insurance, Legal, Educational, Newspaper, Army, Clerical, Governmental, Particulars of leading Institutions and Societies. Paper Covers, 60c. Cloth, Leather Back, 75c. All stationers, or sent postpaid on receipt of price by The Copp-Clark Co., Ltd., Toronto.

KAY'S FURNITURE CATALOGUE No. 306 contains 160 pages of fine half-tone engravings of newest designs in Carpets, Rugs, Furniture, Draperies, Wall Papers and Pottery with Cash prices. Write for a copy—it's free. John Kay Company, Ltd., 36 King St. West, Toronto.

MODERN FIREPROOF CONSTRUCTION—Our system of reinforced concrete work, as successfully used in many of Canada's largest buildings, gives better results at lower cost. "A strong statement," you will say. Write us and let us prove our claims. That's fair. Leach Concrete Co., Ltd., 100 King St. West, Toronto. (tf)

MR BUSINESS MAN, are you progressive? It's up to you to test "Consolidated," our new process carbon paper. Because it costs less. Soft finish, without smutting, and clear, permanent copies. Write for sample sheets and prices. "Consolidated." Stratford, Ont.

"SYSTEMS" stand for all that is best in loose-leaf binders and supplies, letter-heads, statements and in fact your office stationery of every description. Send us samples of what you are using—we will send you prices that will interest you. Business Systems, Limited, Manufacturing Stationers, Toronto. (tf)

WAREHOUSE AND FACTORY HEATING SYSTEMS. Taylor-Forbes Company, Limited. Supplied by the trade throughout Canada. (tf)

SHOP AGENT WANTED.

WE want an agent in every machine shop in Canada where fifteen or more men are employed, to take subscriptions to this Journal. Subscriptions are easily obtained and the work can be carried on by giving a few minutes to it in the noon hour. Liberal commissions allowed both for new subscriptions and for renewals. Write for terms. Agents' Dept. CANADIAN MACHINERY, 143-149 University Ave., Toronto.

When writing advertisers kindly mention having seen the advertisement in this paper.

A GOLD MINE

SAVE YOUR IRON

SLY'S PATENT IRON CINDER MILL
Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the coke contained in your cupola dump, and gangway scrapings. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

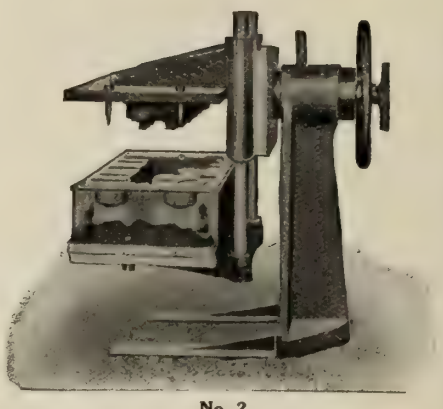
JONATHAN BARTLEY CRUCIBLE CO.

TRENTON, N. J., U. S. A.

MANUFACTURERS OF

Crucibles of Quality



Grimes Roll-Over Molding Machine

No. 1

This is a simple, standard machine, requiring small floor space.

It is perfectly balanced, requiring no counter-balancing mechanism, as centre of gravity is centre of rotation.

No. 2

By means of small hand wheel shown in cut, one man can turn largest flask smoothly and without jerk.

Pattern is drawn by absolutely straight gravity drop.

This machine is adjustable for deep flasks and can readily take care of flask 24 in. x 36 in. and 4 to 12 in. in depth, with maximum pattern draft of 12 in.

Positive adjustable pins at four corners of clamping device, Fig 2, compensate for unevenness of floor boards.

PRICE, f.o.b. cars Windsor, $125.00

HIGH GRADE CASTINGS are not made with low grade materials. Think this over when you see a poorly finished casting in your cleaning room, and remember, if you please, if you wisb to place the pattern in the high grade class, our No. 48 Plumbago will do it, also that the saving in cleaning room expense would pay for three times the necessary No. 48 Plumbago to have made it high grade.

Another vital point is that you have a core wash which will peel clean and not run before the metal. Try our Eureka Blacking, the best core wash on the market.

HOW TO MAKE GOOD CORES ECONOMICALLY

USE GLUTRIN

"Bear in mind that no matter how well your iron is purchased and mixed by expert metallurgists, no matter how hot it comes from the cupola by the best of melting practice, and no matter how perfect and clean a mold you have made, if you put into that mold a poor core, your casting will be scrap and your expert labor instead of yielding revenue will be a complete loss."

We say, without any fear of contradiction, that there is 200 per cent. more GLUTRIN used in Canada than all of the other liquid core binders advertised.

We have customers using it in proportions varying from 1 to 50 to 1 to 125.

There is only one substitute for GLUTRIN and that is linseed oil. GLUTRIN is 20c. per gallon always---linseed oil to-day is $1.11, probably $1.25 to-morrow.

If you have been using linseed oil, have your cost clerk figure out how much money you have lost during the past year. It will make interesting reading.

We will send a barrel of GLUTRIN to any foundry in Canada for trial purposes, with the understanding that, if not satisfactory, same is not to be paid for.

GLUTRIN can be used successfully with any sand known to the coremaker, yet in view of the fact that the variety of these sands is almost without limit, it is necessary, now and then, to prepare special instructions for our users, which we will be glad to do upon request.

REAMING

WITH AN OLD-FASHIONED SOLID REAMER

A single cut reduces the diameter of the reamer—**it is no longer accurate.**

Once re-ground it is perceptibly undersize.

It **all** goes to scrap or with difficulty is ground down to a smaller size.

The large majority **all** go to scrap.

WITH A "PARADOX" ADJUSTABLE REAMER

One Paradox body with one set of blades will ream as many **perfect** holes as nine old style reamers.

One Paradox Reamer with an extra set of blades will do the work of 16 to 20 old style reamers.

Paradox blades are inexpensive.

Paradox holes are round, smooth, straight, and **up to size.**

NINE WORN OUT SOLID REAMERS—have done only the same work as—SIX WORN OUT "PARADOX" BLADES

Ask your Dealer **THE DIFFERENCE IS IN TOOL EXPENSE** Write for Catalog 33

Canadian Agents: H. W. PETRIE, Toronto, Ont. WILLIAMS & WILSON, Montreal, Que.

A New Manufacturing Machine Embodying the Constant Speed Drive

No. 13B

PLAIN MILLING MACHINE

Longitudinal Feed, 14 in.; Transverse Feed, 6 in.; Vertical Adjustment, 12 in.

Because it is of the constant speed drive type and is equipped with a friction clutch on the driving pulley, it can be driven direct from the main line, and is readily adapted to a motor drive.

It is rigidly constructed so that it will withstand the strain of heavy cuts. Note the design of the upright which supports the spindle head and also the heavy base and saddle.

The levers and hand wheel controlling the movements are within easy reach of the operator.

SEND FOR CIRCULAR WITH FULL DESCRIPTION.

Wire Wheels.

Rupert G. Bruce Co., Ltd., Toronto

We are introducing a new line in

GRINDING WHEELS:

Dominion Abrasive Wheels

These wheels are made by the vitrified process, recognized as the BEST in the world. We use the very best emery and artificial abrasives—combined with a special bond of our own.

We produce a fast cutting wheel, which will not draw the temper of your tools and which we guarantee to be thoroughly satisfactory.

To Do Fast Good Work

THIS NEW GAP LATHE IS IDEAL

The extra strong gap gives absolute rigidity. This new lathe has extreme accuracy and speed. The carriage and apron will not spring under the most severe strain. The bed is specially braced and webbed. The headstock construction prevents chattering. Ring oilers give perfect self lubrication. Quick acting locking device on the tailstock. Tailstock bolts adjusted from the top. Double back gears give eighteen distinct spindle speeds. Compound rest graduated to thousandths of an inch both ways. Spindle of high carbon hammered steel in solid chilled bearings. Friction safety feeds give quick changes of threads. Gears and racks cut from solid steel where necessary. Specially graduated dial on gear box. Full equipment, strength, accuracy, solidity and wear.

Headstock construction prevents chattering, and deep oil chambers fitted with ring oilers make spindles and bearings self-oiling and always well lubricated.

Tailstock of a special type, and sleeve is clamped by a quick acting locking device. Tailstock is secured to bed by bolts adjusted from the top where they are easily accessible.

Bed, non-springing and webbed, and braced to secure rigidity.

Gap, vibration absolutely prevented by use of brace supports to carriage.

Spindle, high carbon hammered steel in solid chilled cast iron bearings, accurately fitted and self oiling.

Carriage and Apron, non-springing under severest strain, full "V" bearings and flat bearings in addition on front ways.

Double Back Gears give eighteen distinct spindle speeds, suiting lathe to work on widely different diameters.

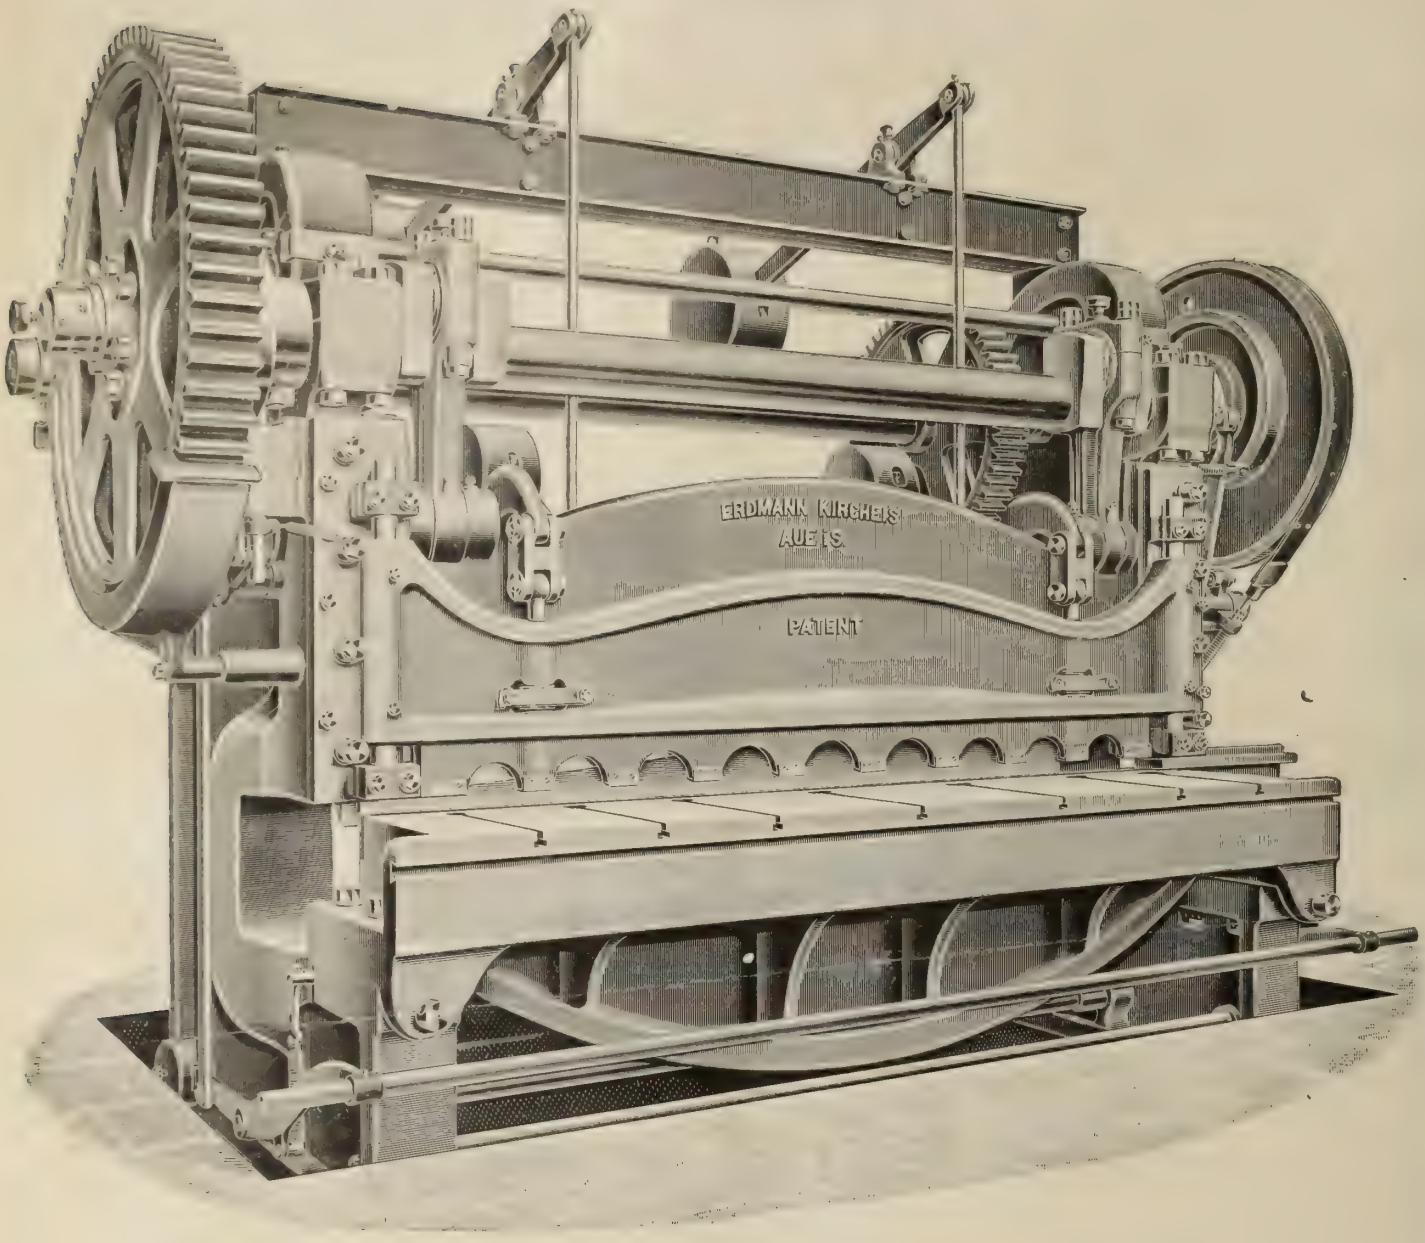
Compound Rest, with graduated base, accurately fitted taper gibs, end adjusted. Screws in both rest and cross slide read to thousandths.

Friction, Safety Feeds, screw and rod feeds cannot be both engaged at the same time. Quick changes of 1¼, 2½ and 5 times thread being cut.

Gears and Racks, cut from solid and steel where necessary.

Screw Cutting, full range of commercial threads provided for.

Equipment, Compound rest, steady rest, follow rest, large and small face plates, wrenches, two-speed, friction countershaft furnished with each lathe.



Accuracy, Strength, Solidity, Wear. These are the paramount features behind all McDougall Machines. Made **to meet extreme demands.**

Type "SA" Motor Driving a Slotter

To properly drive machine tools so as to develop their greatest producing capacity, together with the greatest operating economy, it is necessary to thoroughly study the characteristics of each tool, and to apply a motor exactly suited to its operation.

Westinghouse Types 'S' *and* 'SA' Direct Current Motors

are designed and built especially for this kind of work.

Type 'S' Motors are adapted for constant-speed service and for adjustable-speed service within moderate ratios, 1 to 1½ and 1 to 2. Type 'SA' Motors have auxiliary commutating poles, and are adapted for speed ratios of 1 to 3 and 1 to 4. Circular 1068 gives full particulars concerning both types.

Type 'S' Motor ge Straightening Machine.

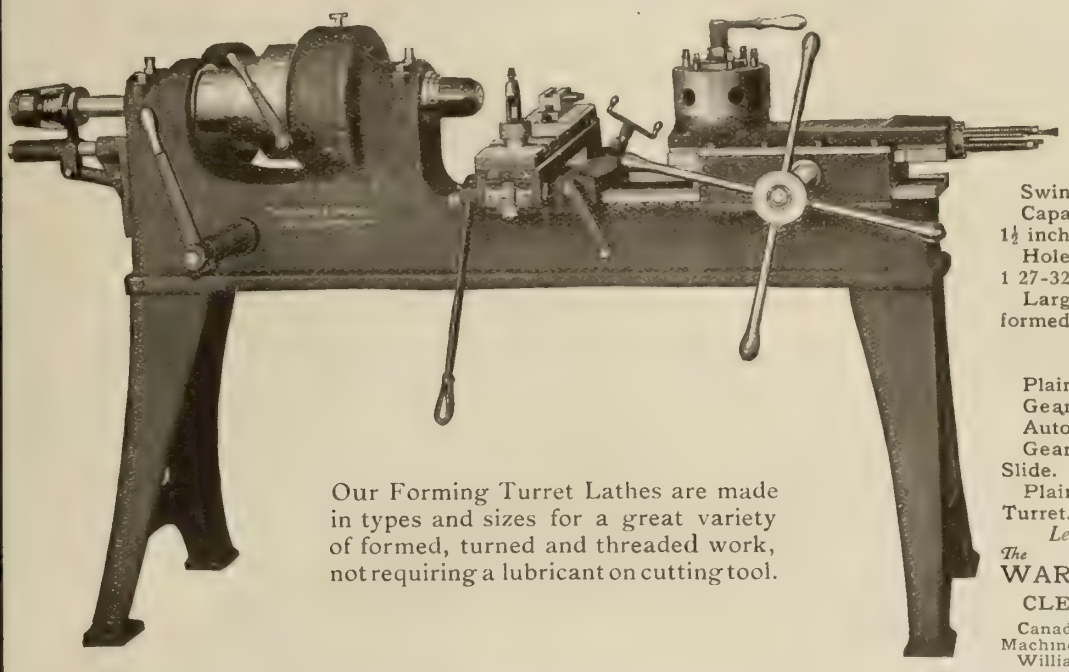
Important Announcement

By special arrangement with the R. K. Le Blond Machine Tool Co., of Cincinnati, we are now enabled to offer for the first time in Canadian Machine Tool History, Lathes made in Canada from designs based on the wealth of experience afforded by the United States market, the greatest machine tool market in the world.

By this arrangement we have obtained not alone the designs, but also the jigs and other fixtures which make for accuracy, interchangeability, and produce unequalled workmanship at a minimum of cost.

The above Lathes represent the very last word in Lathe Construction. Powerful, yet accurate and easily handled—designed for getting the greatest amount of work with a minimum of expenditure of energy on the part of the operator.



Details of construction will appear from time to time in our advertisements.

Cincinnati Cutter Grinder Improvements

Taper Gib for Adjusting Slide
More Substantial Stop Dogs With Fine Adjustment
Stiffer Knee

A FEW IMPORTANT FEATURES:

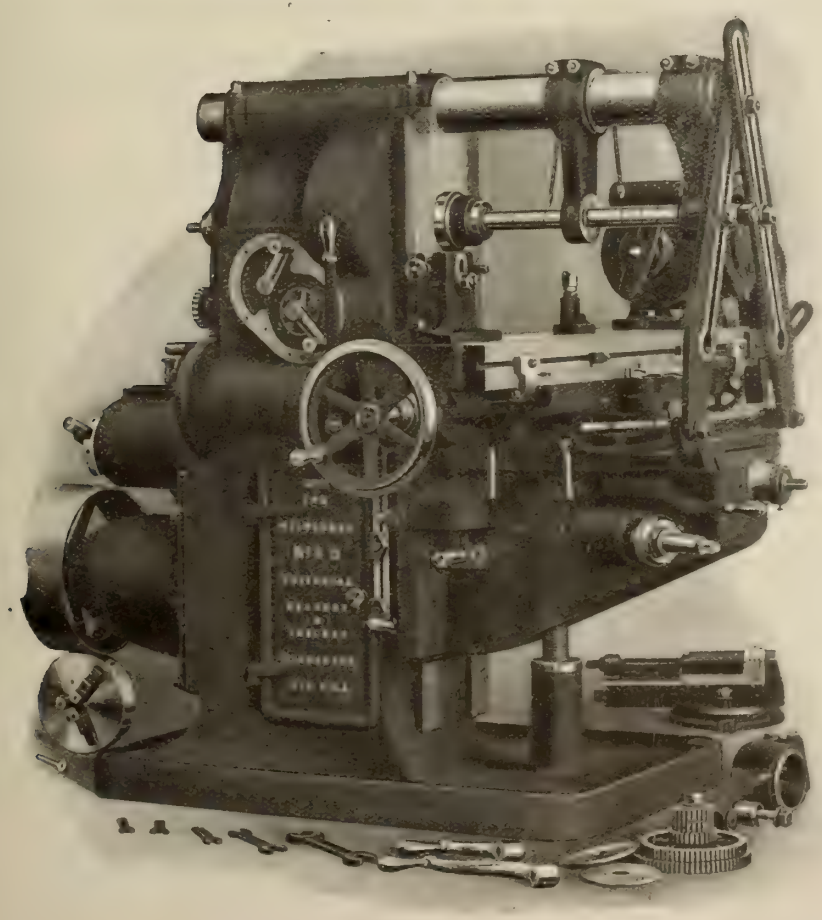
KNEE SWINGS ABOUT COLUMN TO ANY ANGLE
and table swivels about fixed centre on slide, bringing work into any desired position in relation to emery wheels.

GRADUATED DIALS
on all swivels and adjustments.

A QUICK LEVER FEED
for sharpening cutters and also a slow screw feed for other work. Use cup-shaped wheel for sharpening cutters.

HAS MICROMETER ELEVATING DEVICE
for setting cutters or reamers for desired clearance—and on this depends the successful working of these tools.

SOME THINGS IT WILL DO
It will sharpen all manner and shapes of cutters, reamers, etc. Will do internal cylindrical, surface, angular and face grinding.



IT WILL SAVE YOU MONEY
because it will sharpen cutters, reamers, etc., correctly, and quicker than any other similar tool. It is simple and convenient to operate. Any boy can run it.

Ask for Treatise Giving Details of Machine and its Operation.

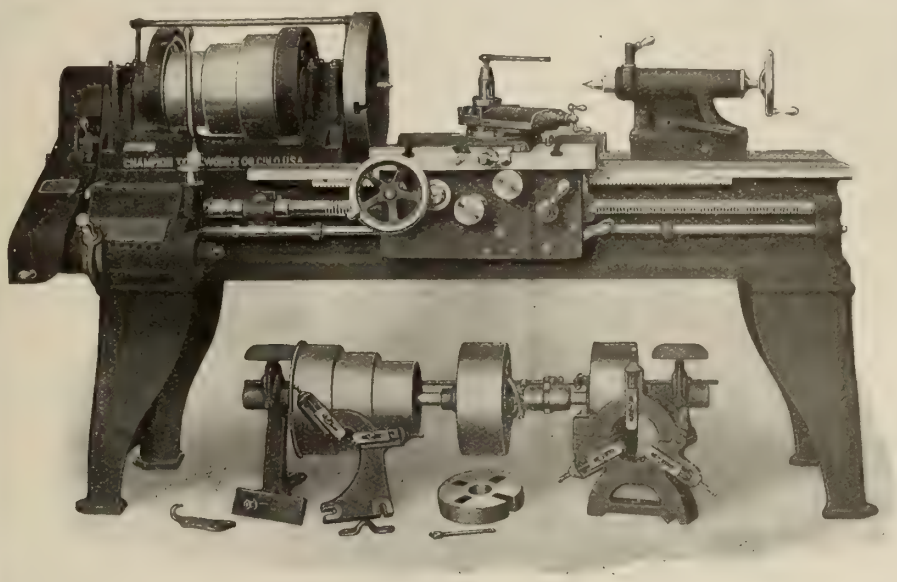
MARINE ENGINES and PUMPS. SHOE MACHINERY A Specialty

BRASS and IRON CASTINGS. BOILERS and REPAIRS.

That we have exceptional facilities at our disposal for the manufacture of all kinds of Machinery —in addition to our business as Brass and Iron Founders, General Contractors and Shoe Machinery Engineers—has been amply proved this year. In the short space of five months, we built and installed all the Engines and Boilers of the new sister steamers "Levis" and "Lauzon," whose trial trips were a complete success. We make a specialty of all kinds of Marine Engine Work, and shall be glad to quote for first-rate products only.

SHOE MACHINERY. Manufacturers of "Non-Royalty" Machines, Metallic and Goodyear, "Fortuna" Skivers, and "Climax" Presses, Sand-papering, Lasting and Loose Studding Machines.



Wire of every description for Slugger and Standard Screw Machines.

High Speed Steel Has a Solid Foundation In a Name That Means Something

Cutting speed attained on cast iron: Roughing cut, 140 ft. per minute—finishing cut, 210 ft. per minute.

In NOVO SUPERIOR you secure a materially increased speed over the high speed steels now in use, the highest quality, greatest toughness, longest life (3 times that of any other) and exceptional ability to cut very hard materials. The cutting edge retains its sharpness from 3 to 4 times longer than other high speed steels. Hardens in oil, air or water, and is now carried in stock in our warehouse in all current sizes, flat, squares and rounds; annealed and unannealed.

Buffalo, N. Y., U. S. A.

The Machine that does it.

Riveting by Lightning

NO RIVETS USED.

You have heard of lightning melting a piece of metal.

That is what's done in a Spot Welder—only the lightning is tamed and harnessed. So tame that you can't feel it (only three to five volts), and harnessed to a machine that a boy or girl can operate with absolute safety. And FAST—well you have heard of "greased" lightning. That's the brand.

One "Spot" will weld two pieces of No. 18 gauge sheet steel together tighter than two rivets. The same machine will weld No. 10 gauge or No. 28 gauge equally as well.

Spot Welded—so called because the small point in the metal the size of a rivet is melted—fused together at the spot where the copper dies touch the metal.

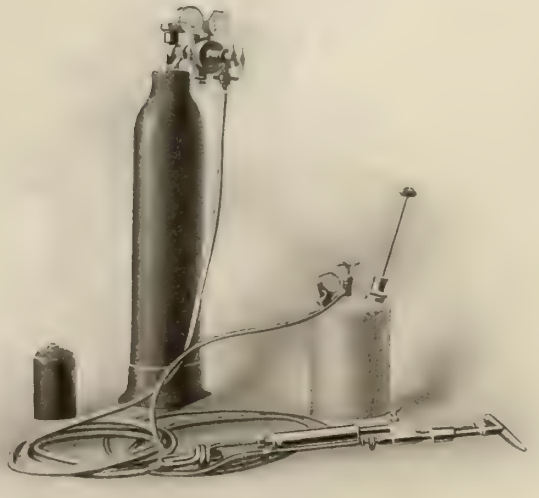
No holes to punch—no rivets to use—no projections to raise—no time wasted.

Our new catalog tells about spot and butt welders, and its yours for the asking.

No Lease. No Royalty. No License.

The "Toledo" Electric Welder Co.

CUMINSVILLE, CINCINNATI, OHIO, U.S.A.



NEW METHOD OF WELDING

Keep Your Scrap Heap Corner Empty

Have your broken castings repaired. Do not lose time **waiting for new castings.** They can be repaired by welding the cracks and broken parts **by the autogenous welding process and made as good as new.**

Blow holes in rough or machined castings of any metal filled up. Holes drilled by mistake filled up. Broken or cracked gasoline engines and automobile cylinders welded. Broken or cracked pulleys, gear wheels, etc., welded. Flanges welded on pipes. Metal added on parts worn out by friction. Teeth renewed on broken gear wheels. Tanks made absolutely water or oil tight. Cutting steel or wrought iron of any thickness and in any position. Cracks and corrosions in boilers a specialty.

Plants supplied for doing the work.
All welding and cutting work undertaken.

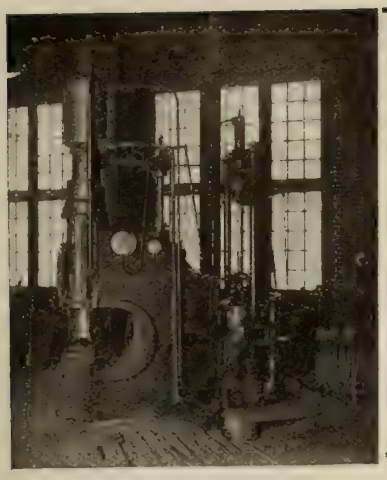
Canadian Agents: Williams & Wilson, Montreal, Quebec; A. R. Williams Machinery Co., Toronto, Ont.

STARRETT TOOLS

ARE THE STANDARD

FOR ACCURACY, WORKMANSHIP, DESIGN AND FINISH

Improved Levels for Testing Shafting, Etc.



In addition to the regular parallel vial, the bases have a cross level which enables one to place or hold the base on a shaft level in its cross section, not canted sidewise: for the shape of a level glass is such that, though true as adjusted on a flat surface, it will not be reliable when canted sidewise. Hence the value of the cross level, not only to test the truth of shafting, but other surfaces which tend to throw the level base into a canting position.

The base of this level has our improved concave running through the length of its base, leaving a flat margin each side, which improves its seat for flat work, while forming an absolutely true and reliable seat for shafting, etc., and it is better than a V groove. Made in 6, 8, 12 and 18 in. sizes, with plain vials and with plain and graduated vials.

Send for free Catalogue, No. 173, of Fine Mechanical Tools.

LET US FIGURE ON YOUR REQUIREMENTS

There's a lot of difference in work in that little difference in words.

Isn't more work a real good reason for substituting New Process Noiseless Pinions for the metal pinions that make your motor drives noisy?

The noiseless pinion is the crowning detail of positive drive, and New Process rawhide makes up into pinions that are interchangeable with metal pinions in all points of efficiency where high speed and constant duty are involved.

New Process Noiseless Pinions by abolishing noise enable the operator to keep plugging away without falling behind his machine's capacity.

Write for our booklet.

METALLIC PACKING

Department of Commerce and Labor

STEAMBOAT INSPECTION SERVICE

OFFICE OF LOCAL INSPECTORS
JUNEAU, ALASKA

October 19, 1910.

Magnolia Metal Company.
113-115 Bank Street.
New York City, N.Y.

Gentlemen:

Before entering this Service I was employed by the Puget Sound Tug Boat Co. of Seattle, Wash. as Chief Engineer of their Ocean Tug "TATOOSH", this vessel being equipped with a triple expansion engine 16" 24" & 40" by 28" stroke, with all piston rods and valve stems packed with the "Metalic Packings." At first we used as "packing metal" a hard fine grained babbitt composition sold on the Pacific Coast under the name of "Packing Metal" the soft rings being cast, and machined in the shop, then scraped to place by hand when installing. The life of these rin was only about 30 days and gave considerable trouble by leaking most of that time, so that eventually I connected the 1/8" vent pipes to the condenser.

Being short of a set for installation at one time I cast a set on mandril and plaster of paris moulds, using Magnolia Metal, with such good results that I at once fitted all rods in a similar manner, the soft rings not being machined or scraped to place in either application, they ran for four months under my care without trouble, and I have since been informed that they were taken out two years after I left the vessel, worn out.

U.S.Local Inspector of Boilers, Juneau, Alaska.

The low coefficient of friction and antifrictional and wearing qualities that have made Magnolia Metal the greatest of all Babbitt Metals for lining bearings, makes it equally valuable as a Metallic Packing. If you have not heretofore thought of Magnolia Metal in that connection we trust that you will not fail to do so in future.

We make Castings, Engines, Boilers, Tanks, and Sheet Metal Work of all kinds, Mining and Brick Machinery.

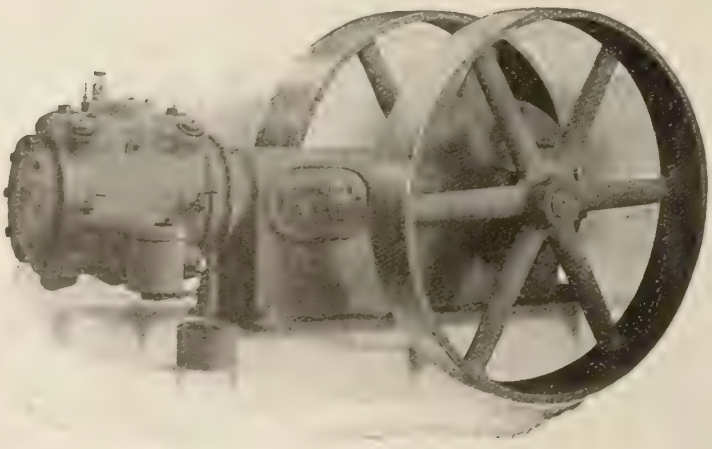
Goodhue Belts

All belts stretch, and the continual cutting out and wasting these short lengths of belting is a very heavy expense! Why not minimize this expense by using

Goodhue Belts

the belts which stretch less by 15 to 25 per cent. than any others? All unstretched parts are excluded in making up these belts, and the greatest care is given to the selection and stretching of each section. "Goodhue" Belts have just the right amount of 'cling' on the pulley, and the price at which they sell, combined with the satisfactory and lengthy service they give, make "Goodhue" Belts the CHEAPEST ON THE MARKET.

According to the conditions under which the belt has to run we recommend: "EXTRA," "STANDARD" or "ACME WATERPROOF" BELTS.



Guaranteed Reliable and Economical

STEEL CASTINGS

By the TROPENAS CONVERTER PROCESS

The above process is used by the leading Open Hearth steel foundries of Great Britain and the United States for small castings, as it gives a superior casting, true to pattern and of the highest grade of steel. We have the most modern and best equipped foundry in Canada for handling small steel castings up to four hundred pounds weight.

High Grade Grey Iron Castings and Pattern Work

Parker Foundry Company, Limited

The Field for Commercial Grinding*

By C. H. Norton * *

GRINDING in various forms has been known to man from the very beginning of history, yet it is doubtful if many engineers have a clear conception of the field for metal grinding. Experience (as a specialist) covering twenty-five years has taught me that the usual thought of grinding is that it is a slow, tedious, expensive, but sure method of obtaining accuracy, and that where great accuracy is not required grinding should not be done.

When, within the recollection of the writer, mechanics made their own solid glue and emery wheels with which to grind small hardened tool work, it did not occur to them that they could do by grinding a certain part of the work that they were using steel tools for, because it was grinding, and was slow. Moreover, all nice work must of necessity take lots of time, because our older mechanics had said so. It did not occur to them that we could ever have better grinding wheels and better machines in which to use them.

It was at this point in our reasoning that the majority of engineers rested and it is here that we find a large number now. All engineers admit the exactness of grinding, but most of them still believe it to be slow.

Appleton's Cyclopedia of Applied Mechanics, published as late as 1893, says that emery wheels are employed mainly for producing cutting edges and for smoothing surfaces. Again it says that in all cases of the employment of emery wheels in place of steel cutting tools, the operation is considerably slower, and it may be laid down as a rule that save upon metal too hard to be operated upon with steel tools, the emery wheel cannot compete with the ordinary lathe, planer, milling tool, etc. My observations convince me that a great many American engineers hold the same views.

What the Wheel Will Do.

As a specialist for many years, I have seen a gradual but sure increase of knowledge of grinding and have noted the widening of the field as the result, but I am not aware that the intelligent study of grinding has been taken up by professional engineers or by any institute of technology. The intelligent use of grinding yields such large returns that it warrants careful study by the very best engineering and scientific minds and a place in the courses of our technical schools. The field is constantly broadening with each year's improvements in grinding wheels and grinding machines, and it is time that men of brains and education took a hand with us to help the world to a better knowledge of the science of grinding and grinding wheels.

The results thus far attained warrant a change of the world's idea of grinding and instead of using it as a synonym for slowness, tediousness and drudgery, it should be a synonym for rapidity, accuracy and economy.

The fact that grinding with the modern grinding machine and grinding wheel (not emery wheel) is that it enables us to size all around work cheaper than by turning and filing, that it takes the place of what we formerly called the finish cut of the lathe and all filing, giving us not a theoretical perfect cylinder or perfect finish, but a much nearer perfect cylinder and finish than we obtained with the lathe. It gives us diameters to such small limits as to be called exact, but whoever insists that none but exact work be ground loses the very pith of grinding, which is economy. Modern grinding means cheaper cost for all work, many grades of work to suit many requirements, and cheaper turning than is possible without the use of the grinding machine.

As a rule, the coarser the turning the greater the economy by grinding. The greatest economy is obtained by the combination of cheaper turning and grinding. It is no longer necessary to turn work smooth, straight or correctly to size, and the lathe is no longer necessary as a precision tool. If it has a carriage traverse of from four to ten threads per inch, has sufficient power to carry high-speed tool cuts at that feed and is well supplied with steady rests to prevent springing of the work, it is ready for co-operation with the grinding machine. It is easier with modern grinding machines and wheels to grind off a given amount of metal when in the form of crude screw threads than in any other form, and with long work having several sizes the grinding requires less time if 1-32 to 5-64 inch is left on the diameter for grinding than if the work is turned carefully to within 0.002 to 0.005 inch. In all cases, accurate turning increases the total cost of production and in some it makes the grinding very expensive. The greatest economy is usually obtained by the combination of grinding with rough turning. Yet there are cases where the least expensive way is to grind direct without turning, notably the greater part of crankshafts of automobiles and small gas engines and very long and slender work where turning is difficult.

*Abstract of paper read at New York meeting of American Society of Mechanical Engineers, December, 1910.

**Norton Grinding Co., Worcester, Mass.

It is not an easy matter to secure such rough turning as true economy requires in connection with grinding. Lack of knowledge of what is needed, coupled with the natural pride the workman takes in doing what tradition says is nice lathe work, prevents the grinding machine from doing what it is ready to do. Our industries are losing much while waiting for the engineer to assume the intelligent guidance of foreman and workmen who, through fear, doubt or prejudice now rob us of the great economies due to modern grinding machines. There is much yet to be learned by foremen and workmen about turning. High-speed steel makes possible much that has not as yet become common knowledge.

The lathe is a very old tool and foremen and workmen have known it for generations, yet I have been unable to find more than two instances where a careful study has been made of the combination of lathe work and grinding to effect the maximum saving. I have observed that lathe men have not tried to remove metal by increasing the number of cuts and using fast traverse. When urged to take coarse feeds to help the grinding machine to effect a total saving, they have invariably said that they were feeding all that the work would stand. It has been demonstrated that three cuts with a carriage traverse of 6 per inch produced certain work in 9 minutes that required 13 minutes to turn in one cut, because the work was so frail that with one cut no faster feed than 32 per inch could be taken. The rough-ridged surface was readily ground by taking one minute more than when the turning was finer, the net saving for the job being three minutes. In many cases the ridged surface requires no additional time.

In another case where the work was quite firm and was being revolved at a very high speed with a view to getting everything possible from the high-speed tool, the turning required five minutes and the grinding one minute. A change was made in the feed of the lathe so that without revolving the work any slower it was turned in one minute, leaving a very crude, crooked and bad-looking piece of lathe work. The grinding then required two minutes, but the net time saved was three minutes. What did it matter how bad looking a lathe job it was if the finished work was perfect and three minutes was saved?

Grinding Makes Old Tools Useful.

There is a rich field for engineers and managers in connection with the lathe and modern grinding. Recent lathe designs provide for high speed of revolution, with sufficient power, quick change to and from back gears, and sufficient rigidity to utilize to the limit high-speed steel, but much work is not of sufficient rigidity to permit the maximum use of the tool at fast traverse and deep cuts. In addition, there are thousands of lathes of old design that will not be thrown away at once. There is, therefore, an opportunity to get much more out of present plants by cheaper turning because of grinding.

Developments warrant the conclusion that we should no longer assume that simply because a tool is a grinding wheel it cannot remove metal and size and

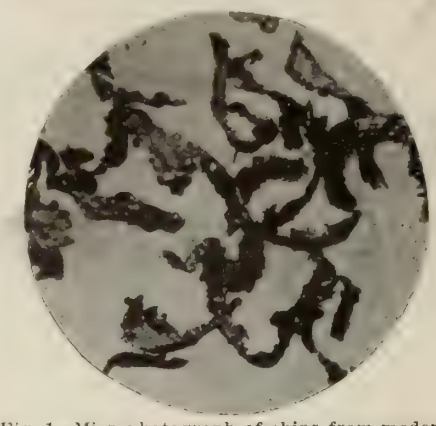

Fig. 1 Microphotograph of chips from modern grinding wheel. Note the resemblance of .. these fragments to lathe chips.

shape work as quickly as a steel tool. Rather, we should use the steel tool when it can be made to remove metal, size and shape work cheapest, and the grinding wheel when it excels. It is no longer to be taken as a matter of course that we can turn, plane and mill faster than we can grind. After all, the real reason we

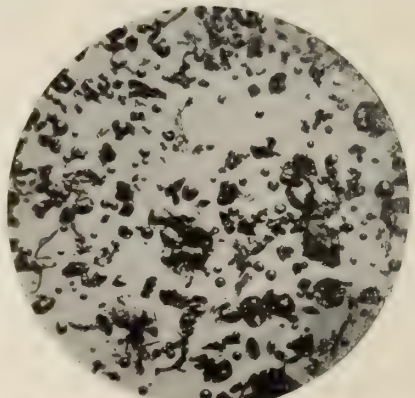

Fig. 2 Microphotograph of chips from modern grinding wheel.

remove metal is to accomplish certain finished results, not simply to secure a certain number of pounds of chips in a given time. Before long I think all progressive engineers will understand that both the grinding wheel and the steel tool have their place for metal cutting. The old thought of abrasion must give way to the new thought of cutting.

While it is still true that poor wheels or good wheels poorly selected and wrongly used will still remove metal very slowly by abrasion, it is also true that the old-fashioned milling cutter, with fine teeth cut by hand with a file, hardened but never ground, and used in the old-time slender milling machine would very slowly abrade the surface. The modern grinding wheel, used in a modern machine by a modern man, is just as surely a milling cutter as if it were made of steel.

The microscope reveals the fact that such a wheel cuts off chips. Fig. 1 is from a microphotograph and clearly shows the chips that are as surely cut off as those made with a steel milling cutter. The grinding wheel used was a modern one made of crystalline aluminum oxide.

Fig. 2 is also from a microphotograph and shows the result of the old-fashioned abrasion described by Webster as grinding to powder. Here we see the effect of great heat, the greater part of the powder being in the form of globules. This is magnified to the same extent as Fig. 1 and shows the vast difference between the old-time abrasion to powder and the present cutting chips. A large part of the energy put into work was wasted in heat, as shown by the very small globules in Fig. 2. The wheel used for Fig. 2 was an emery wheel like those referred to in Appleton's Cyclopedia of 1893.

TARIFF ON RE-ROLLED RAILS.

For some years rails which have been re-rolled in the United States have been admitted into Canada on payment of a duty equivalent to 25 per cent. of the work done on them. The Canadian government has issued an order-in-council which states that a mill has been established in Canada adapted for re-rolling rails used on railway tracks weighing not less than 56 pounds a lineal yard when re-rolled, and orders that the special duty on such re-rolled rails shall be abolished and that they shall be subject to the general tariff. Hereafter rails re-rolled in the United States can only be re-imported on the payment of $7 per ton. It is charged that new rails have been brought in as re-rolled rails.

INCREASING THEIR STAFF.

Merril Z. Fox, for the past six years connected with the Hill & Griffith Co., Cincinnati, has joined the Detroit Foundry Supply Co., of Detroit, St. Paul and Windsor, Ont., as vice-presdent. The Detroit Foundry Supply Co. announce also that they have secured the services of J. H. Lyle who will cover the states of Illinois, Wisconsin and Iowa, and H. E. Moyer, who will cover the states of Indiana, Ohio and the Dominion of Canada. The Detroit Foundry Supply Co. are congratulating themselves on securing the services of these men who understand the foundry lines thoroughly.

Efficiency of Tools and Economy in Their Manufacture

By W. M. Townsend *

Some Points From a Paper Read Before the Canadian Railway Club, Relative to the Making of Cheap and Efficient Tools, Including Milling Cutters, Tools for Lathes, Planers, Shapers and Slotters; Drills and Reamers.

VARIOUS kinds of milling machines are becoming more prominent in removing surplus stock from machine and locomotive parts, hence the necessity of having durable milling cutters.

To obtain an efficient milling cutter there are two points which are essential, namely high speed steel and a spiral or helical cutting edge. The latter quality may not appeal to some, due to the fact that an inserted tooth cutter made from a mild steel body with a high speed steel blade inserted at an angle of about 12 degrees, answers fairly well. This, however, is a great mistake. To obtain a clean cut it is necessary to have a certain and constant angle of rake or lip to the milling cutter. This can be obtained only by having a helical or spiral cutting edge.

To construct the milling cutter that will give the best results and still adhere to the principle of strict economy (the point which I wish to emphasize mostly in this paper), we must first of all consider its diameter. We will first speak of cutters having a diameter of over 6 inches. Keeping close to our principle of economy, we apply to the scrap heap for material; there we will find crop ends of billet steel sawn from the ends of driving axles, which make an ideal body for an inserted tooth high speed steel milling cutter. The scrap value of these crop ends is very small, hence the low cost for the body of the cutter. Now, to procure high speed steel for the blades in an economical manner (which if cut from the steel bar would cost 50 cents per pound), we collect all the broken and short high speed tools that cannot be further used on planers, shapers, lathes, etc. These are hammered into blades $\frac{5}{8}$x1$\frac{1}{4}$x5 inches long. The cost of material for the blades is covered by the cost of labor in hammering out the steel plus its scrap value, which is very small. So much for the economy in procuring material.

We will now turn our attention to the design, upon which depends the efficiency. The bodies, after having been bored, turned, and faced, are milled with slots $\frac{5}{8}$ in. wide, $\frac{3}{4}$ in. deep, 1$\frac{1}{2}$ in. apart, at an angle corresponding to a predetermined helix or spiral. The blades are then fitted and slightly calked. The cutter is then set up on a universal milling machine, and the front of the blades milled spiral. This gives a constant angle of rake or lip from one end to the other. This insures an equal strain along the whole length of the blade. On the other hand, if the blades are merely put in on an angle and not milled spiral, the lip or rake of the cutter is irregular. It can readily be seen that from one end of the cutter to the centre there will be a decreasing lip, while from the centre to the other end of the cutter there will be an increasing drag. This causes an unevenness in the cut and also a tendency to break and pull out the blades on the drag side. So much for cutters having a diameter over six inches.

Inserted tooth cutters with a diameter much less than six inches are not practical, due to the fact that a slot cut at an angle across the top of the cutter body would be very irregular in depth, hence the impossibility of holding the blade. Take for example a blank cutter body 5 inches diameter, 10 inches long, cut a slot through the top at an angle of about 15 deg., you would have a depth of about $\frac{3}{4}$ inch in the centre, while at either end there would be no depth to speak of. This can be avoided, however, by dividing the cutter into short sections, thereby lessening the unequal depth caused by cutting a slot at an angle to the axis of the cutter, but the high cost of this method does not warrant its adoption.

Cost Figures.

The general practice, in making cutters of smaller dimensions, is to use carbon steel costing about 14c. per pound. This is altogether unnecessary and extravagant. Billet crop ends selected from high carbon billets such as are used for driving axles, piston, and side rods, carefully hammered, outclasses in every way the ordinary tool steel. In the first place its cost, hammered to size, is about 11$\frac{1}{2}$c. per pound, as compared with 14c. per pound for tool steel. Secondly, it is tougher, and the teeth will not break when a heavy cut is put on, such as is the case with tool steel, and the cutting edge stands up equally as well. The success of this method, of course, depends upon the treatment of hardening. This, however, is very simple, and consists of carefully packing the tools to be hardened in a mixture of salt and raw bone, placed in an air-tight box, which should be brought and kept to a heat of 1,500 deg. Fah. from 24 to 48 hours according to size, then drawn from the box and quickly immersed in running clear water. There is no need whatever of drawing the temper, as the cutting edge has the correct hardness, while the body of the cutter remains very tough.

Hardening Cutters.

The question that you would naturally raise at this point would be: How deep can cutters be hardened in this manner? I may say that a depth of 3-8 inches can be reached, or in other words the cutter may be ground until the tooth is almost ground away, leaving no space for the chips to get away. When a cutter reaches this stage, it can be annealed, recut, and rehardened, as often as the thickness of material will allow, without affecting the quality of the cutter.

Some three years ago a test was made at our works to determine the advantage of using high speed steel cutters for a certain class of work, namely—milling out jaws of side rods, transmission bars, radius bars, combination levers, etc. It was found that the high speed steel cutters broke from the vibration and pressure brought to bear upon them, whilst cutters of the same design made from billet steel case hardened, did the work very satisfactorily without breaking, running at the same speed and feed. I wish to remind you that what I have said so far regarding milling cutters refers to cutters used for straight milling. Cutters used for milling gears, taps, reamers, and irregular shapes should, in my opinion, be made from high speed steel.

In studying the efficiency and economy of tools, we must not forget to consider the quality and quantity of work required of them.

Tools for Lathes, Etc.

We now come to tools such as are used on lathes, planers, shapers, and slotters. There are many brands of high speed steel on the market at the present time, and I have tried almost all of them, but will not express my opinion regarding their merits, as it would make this paper appear as an advertisement. I believe, however, that if we wish to ascertain which is the most efficient steel, we should give every

*Supervisor of Tools, Montreal Locomotive Co., Montreal.

brand an extensive trial, making an individual record of each, and determining which is the best, as compared to the price paid for it. Different shops have different materials to contend with, and the formulae used in the composition of steel differ, so that some brands are better for cutting one class of material, while other brands are better for cutting other classes of material. This is why I contend that each shop should test out every brand and see which is best adapted for its requirements.

Using High Speed Steel Tips.

High speed steel is an immense item in large machine shops, and great care should be exercised in order to avoid waste. A great saving may be made, by observing the following practice. In making finishing tools, instead of using a piece of high speed steel, say 1¼ in. by 2¼ in. by 15 in. long, costing about six dollars, we go back to the old reliable, and use a piece of billet steel, leaving it as large as the tool post will admit, and weld a tip to it made of high speed steel. The finished cost of this tool is about one-eighth of the solid high speed steel tool and is just as efficient for these reasons: The billet steel is sufficiently strong to withstand the pressure brought upon it for a finishing cut. It does not require dressing any oftener than the solid tool, but it does require a little more care.

I will now explain a little more clearly how this tool is made. As stated before, we take a piece of high carbon billet from the scrap heap, and draw it out to the required dimensions. One end is then scarffed ready to receive the high speed steel tip which is wedge shaped. The toolsmith fits the two parts fairly well together before welding to ensure a neat weld. The parts after having been prepared are then heated, the tip being allowed to heat longer than the body, owing to the necessity of the former being of a much higher temperature than the latter to allow for welding. When both are at a welding heat they are quickly withdrawn, a piece of Lafitte welding compound is placed between them and hammered lightly together. The tool is then reheated, care being taken to place the nose of the tool in such manner that it will be most exposed to the fire, When the required heat is reached the tool is quickly withdrawn and placed between a former under a steam hammer and given a light sharp blow. In case of the tip being displaced, it will not do to try and knock them into place again. The tip must be cut away and refitted, and a fresh piece of the compound used. The tool is then treated in the same manner as a high speed steel tool. These tools have been used until the tip has been ground right down to the weld.

I would not advise making heavy roughing tools in this manner, as the billet steel body would not stand the pressure required by a roughing tool such as is used on a heavy planer. A tool of this description, however, answers well when used on a lathe where the point does not project far from the tool post, also where the cut is continuous and not intermittent, as is the case on a planer. You can readily see where the saving comes in, if this method is only applied to finishing and lathe tools.

Twist Drills.

I will now draw your attention to twist drills. Twist drills made from carbon steel with the exception of jobbers' drills, that is, drills up to ½" diameter, are almost a thing of the past, high speed steel drills having taken their place. The original design of the high speed drill was exactly the same as the ordinary carbon drill with the exception of the material used. This, however, has proven to be inefficient and expensive due to the following reasons: In the first place, to obtain proper results from a high speed drill, it is necessary to have adequate space to allow the chips to free themselves from the drill, as the flutes will soon choke up owing to the increased feed and speed of the drill. The fluted high speed drill has not this advantage. It is expensive for this reason. To make a drill of this design, it is necessary to use a round bar of solid steel, cutting away 50 per cent. of it to form the flutes. Yet there are men who will tell you that this design of drill is the best and cheapest on the market.

Best High Speed Drill.

I will now give my opinion as to which is the best high speed drill and the reason why. A high speed steel drill with a twisted section about half way between the flat twisted section and the standard milled drill is the most efficient and economical, from the fact that it takes just one-third of the steel to make it, and efficient because of the adequate space for the chips to clear, thus preventing clogging and choking. The feed can be doubled due to this advantage. I have found in my endeavor to reduce the cost of tools, that in the average shop where locomotives and heavy machines are built, they have sufficient equipment to make efficient high speed drills with a saving from 10 per cent. to 50 per cent. The same may be said of all kinds of taps, especially those used in boiler construction. These remarks may seem severe to the tool supply men here with us to-night, but this is one point which I feel that I cannot leave out, seeing that our subject is along the lines of economy.

Reamers.

A few words may be said regarding reamers. There are many styles of straight reamers, all of which have their advantages, which leaves me with nothing to say regarding them. Taper reamers are different in their action, however, inasmuch as the whole part of the reamer that comes in contact with the work is cutting equally, whereas, in the straight reamer, the extreme end is the only part that cuts, the rest of the reamer only acting as a guide. It is this difference of action that I now wish to discuss. In all railroad shops there is a great amount of taper reaming to be done; this calls for a different class of reamer. Having visited some of the large locomotive works and enquiring from others, I find that their practice is to use the straight fluted taper reamer —some of them have the teeth staggered, others equally spaced. I beg to state that this style of reamer is decidedly wrong. Reamers that are required to cut equally their full length of flute should be milled with a left hand spiral cutting edge, having an angle of about 20 deg.; the pitch or distance between the teeth should be about ¾", leaving ample space for the chips to clear, thus preventing clogging and tearing of the hole. The advantages of this style of reamer are: It takes about 30 per cent. less power to drive it; it never chatters; it never digs in; the tang does not twist off; the teeth do not break off; they are easy on crank shafts and can be driven with an air motor, where straight fluted reamers would stick. Now this may appear that I am claiming a little more than what is true, but these are actual facts that have been tried and proven.

There are two reasons for the success of this style of reamer, namely, the spiral cutting edge which gives the reamer a shearing action instead of a straight drag (which must necessarily follow with a straight flute), also to the fact that the line of cut parallel to the length of reamer is divided, due to the angular cutting edge which is not parallel to the line of cut. The even and regular curl of chip made by this reamer will also convince you of the correctness of design. The cost of these reamers is a trifle less than the straight fluted reamers, on account of the fewer number of teeth to be cut. This applies generally to reamers having a diameter of 1½" and under, with a flute of from 14" to 16", standard taper 1-16" to 12".

Large Diameter Reamer.

A word or two may be said regarding reamers of large diameter, such as crosshead reamers both for piston and wrist pin fit. For cheapness and durability these may be made in the same manner as solid milling cutters, as mentioned in the previous part of this paper. Select

a piece of high carbon billet from the scrap heap, have the forging well hammered, machine and case harden, and you will have a tool that is equal to the finest tool steel made. You will find that the cost will be about one-tenth of that of good tool steel.

There are many other items of interest whereby great savings can be made, but as our subject covers such a wide area, I must confine my remarks to one or two thoughts in general. Before concluding, I wish to state that AN IMMENSE SAVING MAY BE MADE BY ANNEALING ALL BROKEN AND WORN-OUT TOOLS, IMMEDIATELY THEY ARE OUT OF SERVICE. This being done they should be arranged in open bins or racks, so that when the foreman of the tool room requires material, he looks over his stock of annealed scrap (I mention annealed for the reason that very often a piece of scrap material is available, but it is necessary to wait while it is being annealed) and very often finds exactly what he wants without drawing from the regular stock.

Another feature regarding economy, is the correct distribution. I mean by this that EVERY MAN SHOULD HAVE ALL THE TOOLS HE REQUIRES AND NO MORE. I say this because it is well-known fact that workmen have a habit of collecting and storing up under lock and key, all the tools they can possibly lay their nands on, for their own individual use.

You can readily see that with this practice, if not watched and kept in hand, in large plants many thousands of dollars may be invested and nothing accomplished.

In summing up these remarks, I think you will agree with me, when I say that IT IS ABSOLUTELY NECESSARY IN LARGE PLANTS, TO HAVE A MAN THAT IS FULLY ACQUAINTED WITH EVERY DETAIL OF TOOL DESIGN, TOOL PURCHASING, AND TOOL DISTRIBUTION, TO PROPERLY EFFECT A SYSTEM WHICH WOULD RESULT IN EFFICIENCY, AND ECONOMY. I might add that these duties cannot be expected of the tool room foreman, as his duties confine him to the tool room. Under these circumstances the man appointed to perform the duties of economizing in cost, and designing efficient tools, should have the liberty, to watch all machine shop operations, and to have full supervision of tool room practices. This system is in vogue in some of the large locomotive works in the United States and one that I know of in Canada. This system, if adopted by some of the other large plants, would, I feel sure, bring about results worth noting.

A User's View of the Machine Tool Problem*

By John Riddell**

Some Suggestions Looking Toward Improvement in Lathes, Automatic Screw Machines and Drills, With the Idea of Reducing the Number of Operations That These Machines are Usually Made Capable of, so as to Accord More With Actual Service. The Preblem of Safe-guarding Machinery is Dealt With, to Show That Much yet Remains to be Done to Ensure Immunity From Accident Through Carelessness or Otherwise. The Paragraphs on Noise in Machine Shops, and Muslin Pinions, Will Appeal to Our Readers as Items of More Than Passing Interest in the Record of Progress.

IN factories having a very large output, there must necessarily be a great deal of repetition work, such as cylinders, valves, connecting rods, crank and cam shafts, transmissions, etc. It would seem that most of these parts should be made on very special tools.

Lathes.

The writer has been considering seriously for a number of years the advisability of having instead of standard engine lathes, simple turning machines, to produce such pieces as small shafts, which are required in more or less large quantities. It has been the practice for a long time, when if several lathes were required for any particular department, standard engine lathes would be purchased, which machines would be fully equipped with screw cutting, cross feed, rod feed, compound rest, large and small face plates, and very frequently, with an extra block for large outside turning. Experience has taught us, however, that an engine lathe once placed in one of our shafting departments would, in many cases, wear itself out before having to do any face-plate or chucking work, and very seldom, screw cutting. You can, therefore, see that the cross feed, as well as screw cutting, would be superfluous.

Lathes for this work should be equipped with a powerful rod feed, and with a suitable friction device which would slip if the turning tool met with any obstruction, and prevent serious accident to the machine.

Such machines should be so designed that the screw-cutting attachment and cross feed could be readily applied, if in the future they should be required.

Many attempts have been made to solve the problem of small shaft turning, with more or less success, but many of the machines designed for this purpose have been more or less complicated, which precludes the possibility of putting inexperienced men on to run them.

A lathe to be used exclusively for shaft turning, say from about 2 to 4 inches in diameter, would not require the range of speeds as for a standard engine lathe. The lathe I have in mind should have a range of speed of from about 20 to about 250 revolutions per minute for turning, and two or three higher speeds for filing and polishing. These speeds should possibly be between 450 and 600 revolutions per minute. It is desirable in our case at least to have such machines fitted for electric motors. The motors should have a speed variation of about two to one, which, with two or three gear changes, should give all the speeds necessary for a simple turning machine.

Automatic Screw Machines and Turret Lathes.

The automatic screw machine, in a general way, is made so that six, seven, or eight operations can be performed on most any of them. A very large quantity of work going through them requires but two or three operations at the most, such as milling, threading, and cutting off. Many of the screw machines are so complicated that they will perform the operations whether the tools are actually working or not.

It would seem that machines could be very much simplified by making some do three or four operations only.

The same is true of some larger automatic turret machinery. Some of these machines are designed for boring and facing, but nevertheless, the turret will have five or six positions, all of which operations must be gone through with whether there are but one or two

*Abstract of a paper read before the National Machine Tool Builders' convention.

**General mechanical superintendent, General Electric Co., Schenectady, N.Y.

simple operations to be performed, at the loss of much valuable time.

A great deal might be done toward adapting multiple-spindle heads to single-spindle presses. It is very doubtful if, as at present constructed, it is good judgment to put in too many expensive multiple-spindle drills, for the reason that it takes so long to adjust them for a small number of pieces.

Radial Drills.

Radial drills generally should be so stiffened up as to permit of only the smallest amount of spring to the arm. I believe more drills are ruined by the springing of arms, both under the actual pressure and when a drill is breaking through, than would be if it were not for the springing referred to, as, under the pressure of drilling the arm goes up, and when the pressure is relieved from the point the drills are forced through, and, in many cases catch on the lips and break.

Protected Devices and Wood-Working Machines.

We have had considerable trouble at the Schenectady works of the General Electric Co. lately, in trying to conform to the new State laws, which are very stringent as to the protective devices on machine tools in general and wood-working machines in particular. It is an exceedingly difficult matter to so protect buzz planers and circular saws as to guard against carelessness and the apparent indifference of the workmen, and if someone would devise proper ways and means for protecting such machines he would have the thanks and blessing of the whole manufacturing fraternity.

If an operator has a great many pieces of a similar kind to either saw, plane or shape, he may possibly take pains to apply such guards, which are usually provided, but if, as frequently happens, a man wants to plane one single piece or saw a strip from a board, he will not take time to adjust the safety appliance, and he is very apt to be caught. This would point out the necessity of having some suitable guards which would always be available no matter what the conditions were, and it would seem that people producing this particular line of machinery would conjure up something practicable and effective

Punch Presses.

Punch presses in general are very well designed, but they, like wood-working machinery, are comparatively dangerous to the fingers of careless or dreamy operators. This would suggest automatic feed mechanisms and something to take the piece from the dies after the operation is completed. There have been innumerable devices of this kind exploited, but nothing as yet seems to cover the ground fully.

Another defect in this class of machinery is the fact that in many instances when clutches and other parts come loose, due to wear, they are very apt to repeat the stroke. This frequently happens when a man's hand is between the dies. Such accidents should be impossible until the operator deliberately steps on the treadle.

Noise in Machine Shops.

It has been pointed out that there is a great deal of gear noise in the machine shops of the present day. I am sorry to admit that this is true, but it is not wholly due to the fact that there are more gears used in the construction of machine tools. It is more especially due to the higher speeds at which machines are run to-day, as compared to ten or twenty years ago. Before the advent of high-speed steels 20 feet was considered to be a fair cutting speed for an ordinary steel shaft or a piece of cast iron to be either turned or planed; whereas to-day, we are actually turning shafts at from 75 feet to 125 feet per minute. So it will readily be seen that machines to-day are producing from three to six times more work than they did a few years ago; hence it should follow that there would be more noise due to machine tools producing this extra amount of work. These gear noises are very unfortunate, but we hope by improved gear-cutting machinery and the use of various other materials which have recently been introduced, that this trouble will gradually disappear.

Muslin Pinions.

We have introduced gears at our Schenectady works and pinions made of a high grade of muslin which have been applied to a great variety of uses. We have used one of them on a boilermaker's punch and shear which previously gave considerable trouble, not only on account of noise, but in the actual breaking of the gears; due to excessive back lash and flywheel action on the machine. We had such wonderful success with that particular pinion, which has been running now some two years, that we gradually extended the use until now we are using them on two 10-foot planing machines, which are operated by electric motors and compressed-air clutches, as intermediate pinions for the reverse motion. Heretofore we have tried various substitutes, including bronze, which would go to pieces in two or three weeks; steel would last longer, but made an intolerable noise; rawhide would seem to skrink and burn out quickly, and we very seldom could find anything that would stand the work longer than three or four weeks at the most.

It is perhaps too early to say much about the particular pinions in question, but they have at present been running four months and they have not yet begun to show any signs of distress, and it looks as though their life would be as long as the gears with which they mesh.

Test of Muslin Pinions.

I might ask your indulgence while I describe what has recently been done with a pair of these pinions. As I said before, we have been using them some two years, and are gradually extending their use, and have now fitted up a large department at the Lynn Works of the General Electric Co., where we can produce them in fairly large quantities, but before putting them out in very large quantities we desired to have a life test to destruction, and with this in view we rigged up two railway motors opposed to each other; one of which has a cloth pinion on the armature shaft running into a steel gear on countershaft. On the other end of this countershaft is another cloth pinion engaging with another large steel gear. The other side of this steel gear engaging a cast-gun-iron pinion of the same dimensions as the cloth. This then connects with its shaft and gear to a rawhide pinion on the opposite motor. This particular motor is resisted by rheostats to load the motor which has the muslin pinion. In starting this test it was found that there were no results from a certain load. This load was gradually increased and when after stopping the motors to examine the pinions, through some oversight, an excessive, overload was applied when they were again started. The shock was so severe that it broke about one-half of the teeth from the gun-iron pinion, leaving the two muslin pinions in as good condition as before. Another gun-iron pinion was put on, which also broke. A third was then put on and the load reduced, and the life test has now been running some two or three weeks, and will be continued until some of the gears actually wear out, and not break.

I point this out to show the actual strength of pinions made of this material. So we have reason to believe that with time the noises in machine shops will gradually disappear as they came, without, however, a corresponding reduction in output.

When the belt has become oil-soaked and will not stay on the machine, a good method of cleaning it is as follows: Coil the belt loosely in a tub of sufficient size, and cover with whiting. Be sure that the whiting gets in between the coils of the belt, and it will be only a short time before the whiting will absorb the oil from the leather. It will then only need to be wiped clean to be ready for further use.

Mechanical Drawing and Sketching for Machinists*

By B. P.

A Series of Progressive Lessons Designed to Familiarize Mechanics With the Use of the Apparatus Necessary to Make Simple Drawings, to Encourage them to Realize How Important a Factor it is of Their Equipment, as Well as Being a Profitable Pastime.

THE ability to put one's ideas on "paper" as it is called, is of more import than at first sight appears, and in passing let me say that without this means of developing and conveying ideas from one to another, we would not yet be far removed from the barbaric age in mechanical arts.

Purpose of Course.

You are not to run away with the idea that the purpose is to make a draftsman of you, and having that notion decide that as you are a machinist, this little instruction page need not be read. There will be, it is hoped, no limit to any position of responsibility or trust to which the instruction may lead, but to you particularly is attention directed.

The course will start right at the beginning so as to embrace all grades, and care will be taken to make the work interesting and not too heavy.

To those who have some experience along the lines of our subject, there will be found helpful hints and advice which will amply repay joining in the study.

Difficulties of Study.

Experience goes to show that the difficulty of those who would study in their leisure hours is not one of making a start, but rather a disinclination to keep it up after a short trial. Drawing and sketching is no exception in this respect.

To guard against this trouble I wish to point out a few of the causes why this state of things obtains, so that you may be on the alert when the symptoms appear.

Most people are enthusiastic over anything new, especially if it appeals to their personal interests. Drawing or the desire to be able to make one, appeals to 95 per cent. of mechanics, young and old, not only as a trade help, but also as an enjoyable pastime and a medium by which their imaginative ideas and dreams may assume concrete reality.

The enthusiasm born of this appeal to study, will, as in every other like circumstance, bring a reaction, which coming as it does at a critical time in a drawing instruction course, will require the exercise of a good deal of patient determination.

The impression formed by nine out of every ten who take up study is that the acquirement of knowlege is easy. The prospectus descriptions of drawing courses are largely to blame for this.

The acquirement of knowledge is easy in no sphere or profession, and what is more to the point, the acquirement of the habit of study is less easy still. Too little stress is laid on the necessity of this latter, in fact it is practically ignored.

You have been in the habit of going out every night in the week after your day's work, to have a little legitimate recreation and amusement. You have often thought of studying mechanical drawing, but on account of the want of a proper opportunity you have never done so.

Adjustable Drawing Table.

"Canadian Machinery," which you know, is a reliable journal and to which you have been subscribing for years, comes along in February and outlines just the course you have long looked for. It takes little time for you to decide what you will do, and to be sure you lay your leisure time at its feet,with a generous hand. "I'll give three nights a week to this course, and run in a fourth occasionally."

You make this resolution without counting the cost. You forget that habits have been acquired that are antagonistic to study, and that those necessary cannot be donned in a moment as neither can the others be doffed.

Taking up the course with a rush as it were ensures a reaction, and unfortunately an unhealthy one at that. You are endeavoring to bite off more than you can chew, and my advice is—act cautiously. Set apart one night per week or at most two, and allow yourself to gradually break off the old habits and acquire the new.

Don't believe that it is easy to learn to draw, and that it can be mastered in so many days or weeks. Think of your stage of proficiency in your own particular line, and just figure to yourself how long it has taken you to attain it. Don't imagine that drawing is any easier and you will assuredly succeed.

By looking the matter square in the face thus, you will not get despondent when the reaction sets in and you register your progress as slow. You will not be a "sticker," when you look disgustedly at your drawing board, wondering where all the dirt came from that is on your paper, or amazed at the unintentional contortions you have given to straight lines, the variety of thickness of them, the seeming impossibility of making a circle without showing half a dozen joints and at the number and size of holes your compass needle point has been guilty of.

These experiences are real, troubles which all who would aspire to the making of a simple intelligible drawing will meet, and to minimize and combat which the advice and effort of this instruction course will be directed on your behalf.

Operating Hints.

In order to keep the drawing paper as clean as possible, see that your hands and finger-nails are carefully washed and attended to before commencing work.

Have your coat off, the sleeves of it in contact with the drawing impart dirt more or less.

Never sharpen your pencils over your drawing or in fact, over the table.

Use a hard pencil, say a 3H, it will last longer, need sharpening less often and will assist in keeping the drawing clean.

Wipe the dust from all your apparatus carefully with a clean duster before starting work, and cover up all when you finish each time.

Keep the particles of ground rubber brushed off the sheet, as they being coated with lead from the erased lines, will, if allowed to remain, be crushed against the paper by the movements over them of the squares.

The last instruction on cleanliness is keep your hands as far as is possible from touching the paper. Most people's hands perspire to a lesser or greater extent, and their contact consequently is not conducive to a clean drawing.

*First of a series of an Instruction Course. A lesson will be given each month.

Boiler Design, Construction, Operation, Repairing and Inspection

By H. S. Jeffrey

The Various Points in Connection With Boiler Practice Will be Clearly Taken up in This Series. The First Article Deals With the Boiler Shell, Including Repairing, Factor of Safety, Hydrostatic Test and Number of Courses. The Series will be a Complete Text Book on the Subject of Boilers, and They Should be Preserved for Reference.

THE points considered by the designer in designing a boiler are most important. The boiler should be designed so as to permit proper circulation of the water; to permit the boiler to be easily inspected and cleaned; to prevent undue stresses upon

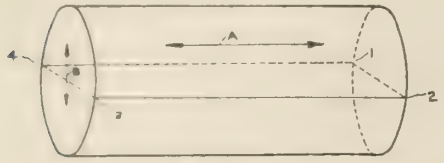

Fig. 1.—

some members and insufficient stresses upon other parts; to permit repairs to be quickly and cheaply made; and the proportion of parts to be such that the boiler will be a free steamer.

(2) Any boiler, whether used or not, will deteriorate. The deterioration is in form of wasting and the wearing out of the boiler, both internally and externally, such as pitting, corrosion, blisters and grooving, all of which means the repairing of the boiler, sooner or later. The essential part of repairing a boiler is to replace the defective part without reducing the strength of the boiler at that point any more than necessary, and, of course, applying the patch or new member in a manner to make the boiler as serviceable or as near as serviceable as formerly.

The foregoing can best be accomplished by the mechanic understanding the underlying principles of boiler design and construction. This being the age of specialists, many of those engaged in boilermaking are not well posted on the forces acting upon the boiler. The

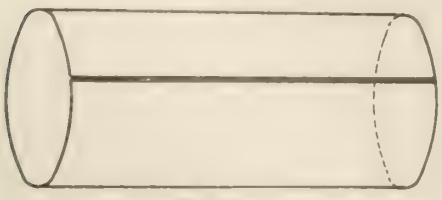

Fig. 2.—

riveter will understand fully about riveting; the flue man about the installation of flues, and others thoroughly acquainted with their respective branches, but the foregoing named specailists not being versed in boilermaking in all its branches are not in a position to advise as are all-around boiler makers with a technical education.

The repairing of a boiler is really an independent branch of boiler construction; it is re-construction. Boiler repairing could be more cheaply and better done if those making the repairs had knowledge of the forces acting upon the boiler, as well as the knowledge acquired by the operating engineer from constant observation of the boiler while in service, and especially the practicability of a patch or new member as applied.

The Boiler Shell.

(3) The boiler designer in deciding upon the diameter of the boiler shell must bear in mind the working pressure per square inch, the factor of safety, the efficiency of the longitudinal seam, the tensile strength of the plates and their thickness, and the type of boiler. There are also practical considerations which he must take into account, and which will be mentioned later.

A boiler shell or cylinder has two forces tending to rupture it. The arrow A, Fig. 1, indicates the force acting on the transverse plane, or cross-wise of the vessel. The arrow B indicates the force acting on the longitudinal plane, or lengthwise.

Though the steam pressure per square inch is the same throughout the boiler, the force acting on the transverse plane, generally called the girth plane, is about one-half the force acting on the longitudinal plane.

In Fig. 1, the vessel is shown seamless, and in order to explain fully the foregoing respective forces a concrete case of a seamless shell of 55,000 tensile strength, 66 inches in diameter by 14 feet in length, and of plate ⅜-inch in thickness will be given.

The force acting on the girth plane will be equal to the cross-sectional area multiplied by the working pressure per square inch. With a working pressure of 100 pounds per square inch the total force will be:

$66 \times 66 \times .7854 \times 100 = 342{,}100$ pounds.

The force resisting the foregoing is the strength of the solid plate in the transverse plane. The area of the plate is found by multiplying the circumference by the neutral diameter, which is equal to the inside diameter, plus one thickness of plate, or 66 inches plus ⅜ inch, making $66\frac{3}{8}$ inches.

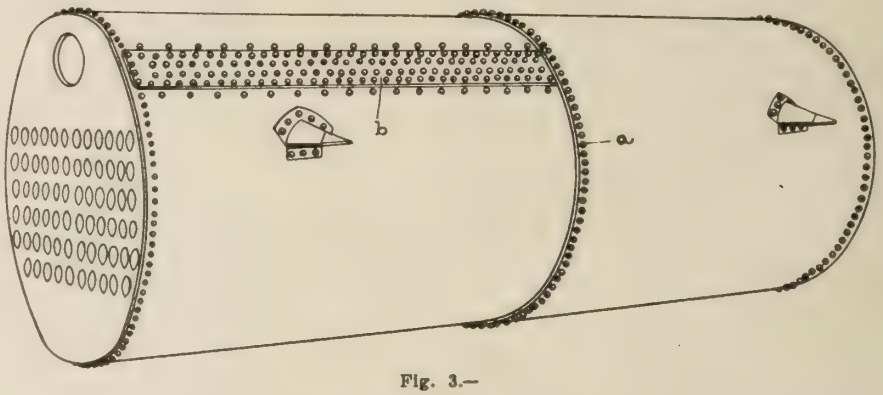

Fig. 3.—

Then the area of the plate of the girth plane upon which the force will act is:

$66\frac{3}{8} \times 3.1416 \times \frac{3}{8} = 78.2$ square inches.

The strength or the resisting force of the plate of the girth plane will then be:

$78.2 \times 55{,}000 = 4{,}301{,}000$ pounds.

The force acting on the longitudinal plane is equal to the area indicated by points 1, 2, 3 and 4, Fig. 1, times the working pressure in pounds. Since the vessel, Fig. 1, is 66 inches in diameter and 14 foot, or 168 inches in length and the working pressure is 100 pounds per square inch, the total force acting on the longitudinal plane will be:

$66 \times 168 \times 100 = 1{,}108{,}800$ pounds.

The resisting force of the plate of the longitudinal plane will be the length of the vessel from points 1 to 4, and points 2 to 3, Fig. 1, times the thickness of the wall. The length of the vessel having already been

• Copyright by The MacLean Publishing Company, Limited.

• First of a series of twelve articles on this subject.

stated to be 168 inches between points 1 to 4, the combined length from points 1 to 4, and points 2 to 3, is twice 168 inches, or 336 inches. The thickness of the wall of the vessel being ⅝-inch and the tensile strength of the plate being 55,000 pounds, then the resisting force is :

336 x ⅝ x 55,000 equals 6,930,000 lbs.

Since the longitudinal seamless plane has a resisting force of 6,930,000 pounds and the total force acting on said plane is 1,108,800 pounds, the ratio between the ultimate strength and the acting force is :

$$\frac{6{,}930{,}000}{1{,}108{,}800} \text{ equals } 6.25$$

The calculations in the foregoing paragraphs brought out that the force acting on the transverse plane amounted to 342,100 pounds, being resisted by a force of 4,301,000 pounds, therefore, the ratio between the ultimate strength and the working pressure is :

$$\frac{4{,}301{,}000}{342{,}100} \text{ equals } 12.5$$

Examination shows that the transverse load is approximately one-half the longitudinal load, and, accordingly the ratio between the ultimate strength and

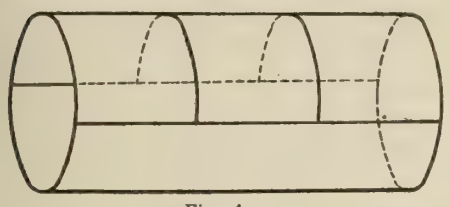

Fig. 4.—

the applied load on the transverse plane is about twice the ratio between the ultimate strength and the applied load on the longitudinal plane.

Longitudinal and Girth Seams le

(4) Prominent among the many problems which arise in designing a steam boiler is that of the arrangement of the courses and riveted joints. Very few vessels are made seamless, and, accordingly the rings or courses composing the vessel must be connected together in some manner.

This is accomplished by the installation of rivet holes in the plates and then securing the plates to one another by over-lapping and riveting, or by butting the plates and securing them by butt or welt straps riveted to the ends of the plates.

In Fig. 2 is shown a course of a boiler as it would appear when rolled approximately into shape, and no holes installed for the seams. The calculations for a seamless course brought out that the vessel was twice as strong through the transverse plane as the longitudinal plane, and for this reason the designer can make the girth seam a, Fig. 3, single-riveted, while the longitudinal seam must be made double-riveted, or triple-riveted, and with a high-pressure boiler the longitudinal seam is made a triple-riveted butt double-strapped joint with the outer row of rivets in single

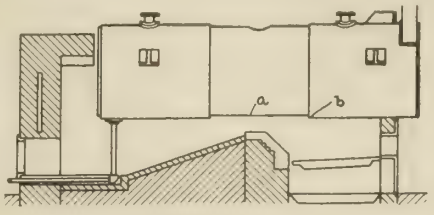

Fig. 5.—

shear, all as shown at the longitudinal seam b, Fig. 3.

The installation of the rivet holes does not make it possible to make the boiler at the longitudinal seam as strong at that point as the solid plate elsewhere in the longitudinal plane. The strength of the longitudinal joint will depend upon the type of riveted joint and the size and pitch of the rivets. The solid plate is to be considered as 100 per cent., and this is the case irrespective of the thickness of the plate, or its tensile strength.

Since the longitudinal seam is less than 100 per cent., and it is necessary when computing the working pressure to consider the strength or the efficiency of the longitudinal seam, the following formula, which is used by most authorities for ascertaining the allowable working pressure of a vessel, is given :

Where :

TS equals tensile strength of plate in pounds.
T equals thickness of plate in inches.
D equals diameter of boiler in inches.
F equals factor of safety.
A equals allowable working pressure per square inch.

$$\frac{TS \times T \times 2 \times E}{D \times F} \text{ equals } A$$

Factor of Safety

(5) It is not advisable to work a boiler or any other structure at or near its ultimate strength. There should be con-

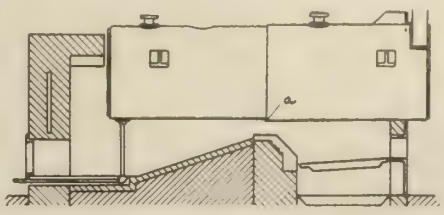

Fig. 6.—

siderable difference between the ultimate strength and the allowable working pressure. The ratio between the two is called the factor of safety, and in boiler construction the minimum factor of safety allowed by most authorities is 4.

The factor of safety cannot be set in an off-hand manner ; it must be decided by the circumstances of the case. Thus a boiler having all holes drilled in place and constructed with a double-strapped butt joint, will—and justly so—be allowed a lower factor of safety than a boiler of like size and design, but with the holes punched.

Many of the authorities have established the minimum factor of safety at 4, and then add to it certain amounts in accordance with the type of riveted joint and the grade of workmanship. Such rules and regulations encourage good design and workmanship.

A high factor of safety does not indicate that the boiler is better constructed than a like boiler with a lower factor of safety. The minimum factor of safety should not be less than 4—and a boiler properly designed and constructed with a factor of safety of 4 is a safer boiler than one poorly designed and constructed with a factor of safety of 6.

The Hydrostatic Test.

(6) Merely because a steam boiler withstands a given hydrostatic or cold water test, it is no sign that the boiler is safe. The test itself, if improperly applied—that is, an excessive pressure applied, will injure the boiler. The elastic limit of the steel, which is about 50 per cent. of the ultimate strength of the plate, must be taken into consideration.

The elastic limit means the point where the applied load begins to produce a permanent elongation. Up to that point the metal will yield slightly, but when the load is removed the metal will return to its original length. It is never safe to place a load on any structure beyond this point. A boiler constructed for a working pressure of 100 pounds steam pressure per square inch, factor of safety of 5, would burst at approximately 500 pounds pressure per square inch, but the danger point would be reached at approximately 250 pounds (or the elastic limit) if the square of the section of plate in the longitudinal seam is equal to the shearing strength of the rivets.

This is assuming that the efficiency of the riveted joint is determined by the plate, maximum net section of plate, and the efficiency of the rivets exceeds the latter to some extent. With a factor of safety of 4, the boiler will show signs of distress at 200 pounds pressure, for as soon as the elastic limit of the plate is reached the plate begins to reduce in area, consequently a loss of strength ensues which cannot be regained.

It must not be assumed that a boiler constructed for 100 pounds pressure,

factor of safety of 4, will be able to sustain a hydrostatic pressure of 200 pounds per square inch without serious and permanent injury to the plates. The hydrostatic test should at all times be less than the elastic limit, and a cold water test of one and one half times the allowable steam working pressure is ample.

Number of Courses in a Boiler Shell.

(7) In the earlier days the designer was forced to give consideration to the size of plates obtainable. With the introduction of larger and heavier machinery in the rolling mills, plates are now made of greater thickness and length and width than formerly, and, accordingly the number of sections or courses now composing a steam boiler are fewer than before.

The steam pressure per square inch of steam boiler has increased gradually in late years, and this with the changes in the plates has caused the whole field of boiler designing and boiler constructing to undergo marked changes within the past fifteen years.

The number of courses to be used in a horizontal tubular boiler is a question upon which boiler designers are not all of the same opinion. Some have advocated making large tubular boilers of one course. This is the practice for the shells of small size tanks and air drums and like structures, and has given satisfactory results, but the one course large size boiler has been anything but a success, and for reasons which will be hereinafter given.

Others have advocated constructing horizontal tubular boilers with a long bottom course and several upper courses as shown in Fig. 4. There is no advantage in this form of construction in regards to the costs of manufacture. This plan of construction is used principally with large tanks, such as used by railroads for transporting oil. Vessels of this design have given satisfaction in the foregoing field, but what few boilers of this design, where the shell is in contact with the flames and hot gases, have been a source of trouble almost from the day they were installed.

The majority of boiler manufacturers are now constructing tubular boilers with either two or three courses. The tendency is to favor the two-course boiler. This is due to the fact that a two-course tubular boiler can be constructed somewhat cheaper than a three-course boiler. The boiler manufacturer in order to meet the demands for boilers at low figures, naturally, designs and constructs the type which has the lowest first costs.

While the purchaser desires to purchase everything as cheaply as possible, which fact has been deeply impressed upon the mind of the manufacturers, the purchaser should take into consideration the whole field and not merely first costs.

The three-course tubular boiler as shown in Fig. 5, is favored as the girth seams a and b stiffen the shell sheet, while the stiffening of a two-course boiler as shown in Fig. 6, is only one-half that of the three-course boiler. Of the above respective types of boilers, experience has shown that a two-course boiler with long longitudinal seams is not as satisfactory as a three-course boiler with short longitudinal seam, and as a general rule a three course boiler is more durable than a two-course boiler.

There is also another point in favor of the three-course boiler. The girth seam of a three-course boiler is well away from the bridge wall, the same being indicated in Fig. 5, while the girth seam of a two-course boiler is directly over the bridge wall, the same being indicated in Fig. 6. With a three-course boiler the impinging flame strikes the shell sheet at about the point a, Fig. 5, while with a two-course boiler the impinging flame strikes the shell sheet at or near the girth seam a, Fig. 6.

While it is true that the girth seam b of a three-course boiler is directly over the furnace—and this is not the case with a two-course boiler—the girth seam b, Fig. 5, does not come in contact with the impinging flame as does the girth seam a, Fig. 6.

The foregoing considerations are uppermost in the minds of boiler designers when designing tubular boilers. In addition thereto comes the question of repairs. It has been found that a two-course boiler is more liable to bag from scale, mud and grease than a three-course boiler, and further when trouble of this character arises, a three-course boiler tends to prevent the bag from spreading over a great distance, and accordingly the repairing is usually less with a three-course boiler than a two-course boiler.

Machining a Flexible Joint for the Toronto Intake Pipe

The Variation in Levels, Where the Intake Pipe Extension is Being Laid at Toronto, Necessitates the Changing of Direction by Using Ball and Socket Joints. The Machining of These Large, Flexible Joints is an Interesting Problem Which was Solved by the Canada Foundry, Toronto.

THE intake for Toronto water supply extends out into Lake Ontario. For some time trouble has arisen from sand and brushwood collecting around the mouth of the intake. The Toronto Board of Control and Council were impressed with the idea that purer water could be obtained farther out in the lake and that the above troubles could be eliminated.

City Engineer Rust and Assistant Engineer Fellows were instructed to extend the intake 500 feet. The extension had to be made in deep water and the pipe laid on a varying level of lake bed. The extension has therefore created a number of problems to be solved.

One of these problems was to make provision for the change in direction of the pipe due to the difference in levels. For this purpose it was decided to use two ball and socket joints. The ball and joint must fit perfectly, otherwise a leak would result. The machining of these joints was therefore a very fine piece of work, necessitating absolute accuracy. Two joints were made to fit in between three sections of pipe, each 168 feet long, 72 inches diameter. The plate used was 5-8 inches thick, channel riveted to cast steel flanges and turned to suit the radius of the bearing. Fig. 1 shows the finished ball joint.

The contract for the flexible joints was given to the Canada Foundry Co., Toronto, and Mr. Loach, the superintendent devised the plan of machining the work. This taxed the machinery to a certain extent. It was finally accomplished on a large locomotive wheel lathe built by the John Bertram & Sons Co., Dundas.

Operations.

The machine operations on the ball joint were as follows:

(1) The casting which is 7 ft. 3 in. outside diameter finished, was put on a 10 ft. boring mill, bored and faced on outside and given a roughing cut to remove uneven metal.

(2) It was sent to the boiler shop and riveted onto piping with flange. This piping was short length and steel flange

made it easy to hold the casting on the face plate of the wheel lathe.

(3) The rigging was composed of a ball-bearing turntable ordinarily used for heavy drill press work, fastened in the exact centre of the lathe underneath the casting; a bar connected the turntable with the tool post which was removed from original fittings and placed on a surface plate. A screw feed attachment for moving tool post on a perfect radius resulted in an excellent job and an exact circular surface.

Mechanism Explained.

The tool post rested on the surface plate A, Fig. 2, and was connected to a ball bearing centre by the rod J, thus making a solid connection between the two. The tool post was fastened to a plate with a lug E. The ratchet D was fastened to the screw B. By operating the ratchet, the tool post resting on the shoes F, was drawn towards the lug C which was permanently fixed to the surface plate.

The casting has a steel pipe fastened to it. This pipe has a flange by which it was bolted in the lathe as shown at H. On account of the weight of the ball joint, it was braced from the face plate shown on the right of the illustration. Four braces were used, being fastened solidly by means of turnbuckles as shown at H. This arrangement prevented any moving of the work during the machining operations. The result was a perfect ball joint.

PERSONAL.

Geo. D. Leacock has been appointed travelling representative for the Packard Electric Co. for the territory between Kingston and the Soo. His headquarters will be in Toronto.

* * *

Laurence T. Walls, of the Dominion Wire Mfg. Co., Montreal, has accepted a position in the Winnipeg office of the Steel Co. of Canada, as assistant to Mr. Hanna, manager of the Northwest sales branch of the Steel Co.

* * *

J. T. Brower, manager and engineer of the Structural Steel Co., Longue Point, will become general manager of the National Bridge Co., of Montreal. He will take charge of the National Bridge Co. on March 1.

* * *

Thos. Moore has been appointed manager of the Belleville Rolling Mills, which is a branch of the Steel Co. of Canada. Mr. Moore was connected with this firm shortly after it started in business, but resigned to take position of salesman with the Canada Screw Co., Hamilton.

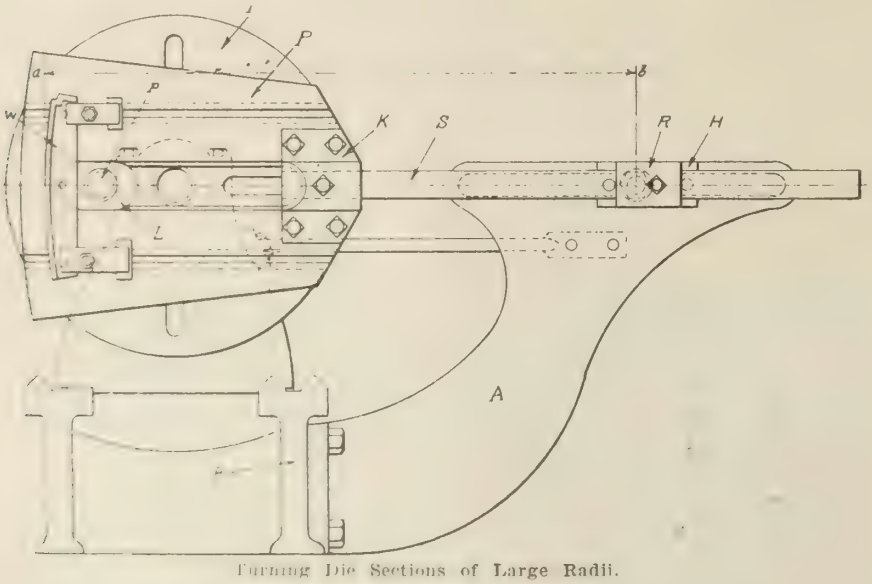
MACHINE SHOP METHODS AND DEVICES

Unique Ways of Doing Things in the Machine Shop. Readers' Opinions Concerning Shop Practice. Data for Machinists. Contributions paid for.

TURNING DIE SECTIONS OF LARGE RADII.



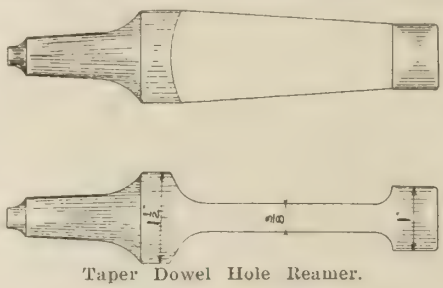
By J. H. Rodgers.

The accompanying sketch shows an attachment placed on a gap lathe for the purpose of turning the portion of a circle of large radius, as found on a blanking die for pail or tub sections, and other similar work, within the range of the attachment.

The large bracket A is secured to the bed of the lathe B in such a position that the back of the plate P rides on the surface of the face plate F.

The plate P is kept in contact with the face plate F by the pin P and the block L. At the rear of the plate P is secured a bracket K, which carries one end of the shaft S, the other end passing through the swivel block R, which is free to turn in the piece H. H can be secured in the slot as shown to suit the radius being turned as a—b.

The pin P is secured to the face plate in a position that gives the desired travel to the work W, which is fastened to the plate P.



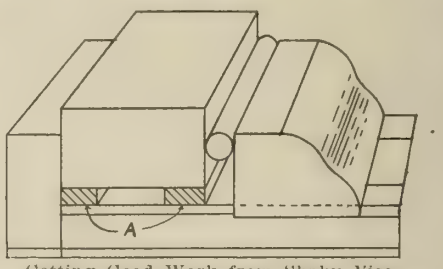
Turning Die Sections of Large Radii.

As the lathe spindle revolves it gives an up and down motion to the work, similar to the action of a shaper, only the tool is stationary, while the work is in motion.

TAPER DOWEL HOLE REAMER.

By L. R. Brown.

The sketch and description refers to a tool used in the C.P.R. Angus shops, Montreal, for reaming taper dowel plug holes in locomotive driving box crown brasses. It is cheaper to make, cuts cleaner, quicker, and gives better results than the ordinary fluted reamer; does not bind, and can be sharpened in a few minutes on an ordinary flat emery wheel, and saves toolroom time by doing away with the necessity of having an experienced toolmaker grind it.



Taper Dowel Hole Reamer.

The tool is made from 1½ inch round stock; the shank being turned to fit machine spindle, the body turned to required taper and milled out to ⅜-in. thickness, leaving a 1-in. diameter turned pilot end, to steady the tool in operation, and ensure a true hole. The cutting edges are filed to give the necessary cutting clearance, and these only should be ground.

GETTING GOOD WORK FROM "SHAKY" VISE.

By G. B. Marquette.

Most of us have experienced trouble in getting a block or key which is to be held between the jaws of the vise to lay flat on the parallel bars A, just as the movable jaw tightens on the job, the slackness in the jaw lifts the piece of work. Time after time the vise is slackened and tightened again. It would not be hammered down. Time is being wasted for the machine stands idle. Take a piece of ⅜-in. rod, insert between the movable jaw of the vise and the work and tighten. Instead of the slackness in the jaw lifting our work, the piece of ⅜-in. round will accommodate itself to the movement of the jaw and roll slightly, leaving our piece of work perfectly flat, and upon the top face being machined will be found to be perfectly parallel.

Getting Good Work from Shaky Vise.

TO SAW SHEET IRON OR PIPE.

By G. B. Marquette.

In the machine shop we frequently have to make a template of sheet iron, and in order that we may not distort the material we are obliged to use a hack saw. Immediately we attempt to use it, we are in trouble, for the thin sheet iron just drops between two of the teeth and stops there. To get over the difficulty simply reverse the saw blade in the frame and proceed in the usual way. It will neither catch or break, and cuts just as well.

RUSSELL AUTOMOBILE BRAKE.

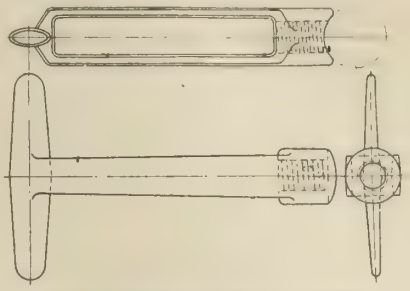
The construction of an automobile brake is not very generally understood. The ones shown in Fig. 1 and used on the Russell cars, manufactured by the Canada Cycle & Motor Co., Toronto, will therefore be of interest.

In the end view, the moving element is shown hatched. In an automobile brake there are two main considerations, namely, lightness and positiveness of action, particularly the latter feature, as such a brake must never fail to work when required. For this reason, each brake has two clutches, the ordinary, and the emergency.

The outer brake shoe is part of the "ordinary" equipment. It is put in operation by moving to the right the lever 6649 (shown to the extreme right of the cut.) This tends to bring closer together pins 3012 and 1188, tightening

the brake on the outside of the moving shell. When the brake is released, spring 5918 separates the two elements of the brake shoe, which are hinged on the far side. As this brake is in constant use, the friction face wears, loosening the brake on the moving element, necessitating a further movement of the brake lever to tighten the brake. For that reason it is made adjustable for wear by threading the bolt connecting the two halves of the brake, as shown. Customarily in most brakes, a nut and jam nut are employed, requiring a journey under the car each time adjustment is needed. The Russell car uses a simple contrivance to overcome this, using the lock nut shown at 5921, and more clearly in Fig. 2. The connecting bolt passes through a hole in pin 3012, and the lock nut, which has its face rounded out, conforms to this surface, and is positively held in the one position by the spring holding it there. This permits of only half turn adjustment, which meets requirements.

For emergency purposes, there is an inner clutch, as shown, and which is of a much more positive nature. It consists of a toggle joint operated by lever 6321 (shown dotted inside view.) The shoving to the right of link 797, creates a tremendous outward pressure of the brake on the moving element, stopping it almost instantly if applied with sufficient force. It is also adjustable as shown by a small turnbuckle threaded right and left hand. A spring 6585, holds the shoes out of position when



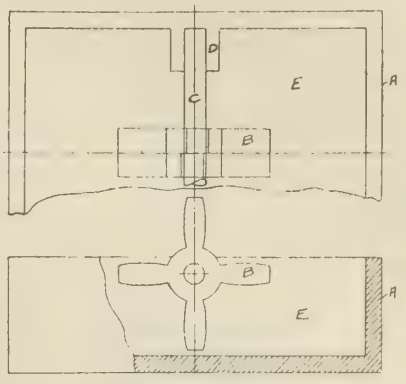


Fig. 2—External Brake Adjuster.

not required. It is not adjustable, as this is unnecessary, the brake being only put in commission in cases of emergency.

WORM GEAR OILER.

One of the most difficult pieces to keep properly lubricated, is the worm gear on a vertical shaft, for there is nothing to retain the oil or grease like there is when it is placed horizontally. This has been the experience of Wm. Kennedy & Sons, Owen Sound, who have improvised the simply device shown in the accompanying sketch, to overcome lubrication difficulties of worm gears on vertical shafts. The fixture consists of a shell A in which are paddles B, on shaft C, which is supported in cast bearings, projecting from shell A. The box A is placed directly beneath the worm to be lubricated, in such a way that the teeth of B, mesh with the worm teeth. Of course, B must be made specially for different worm pitches. The space E is filled with a semi-fluid grease, which is lifted up into contact with the worm as each tooth of B rises. The grease must be semi-fluid to insure the space around B being always filled.

There are two wheels B, one placed slightly behind the other, as shown in the plan view, thus giving pitch to the oil wheels, to match the worm. The whole device, while very simple and crude, meets the requirements extremely

Worm Gear Oiler.

well. Gears examined after long use, showed practically no wear, whereas, before using this method, the wear was quite considerable.

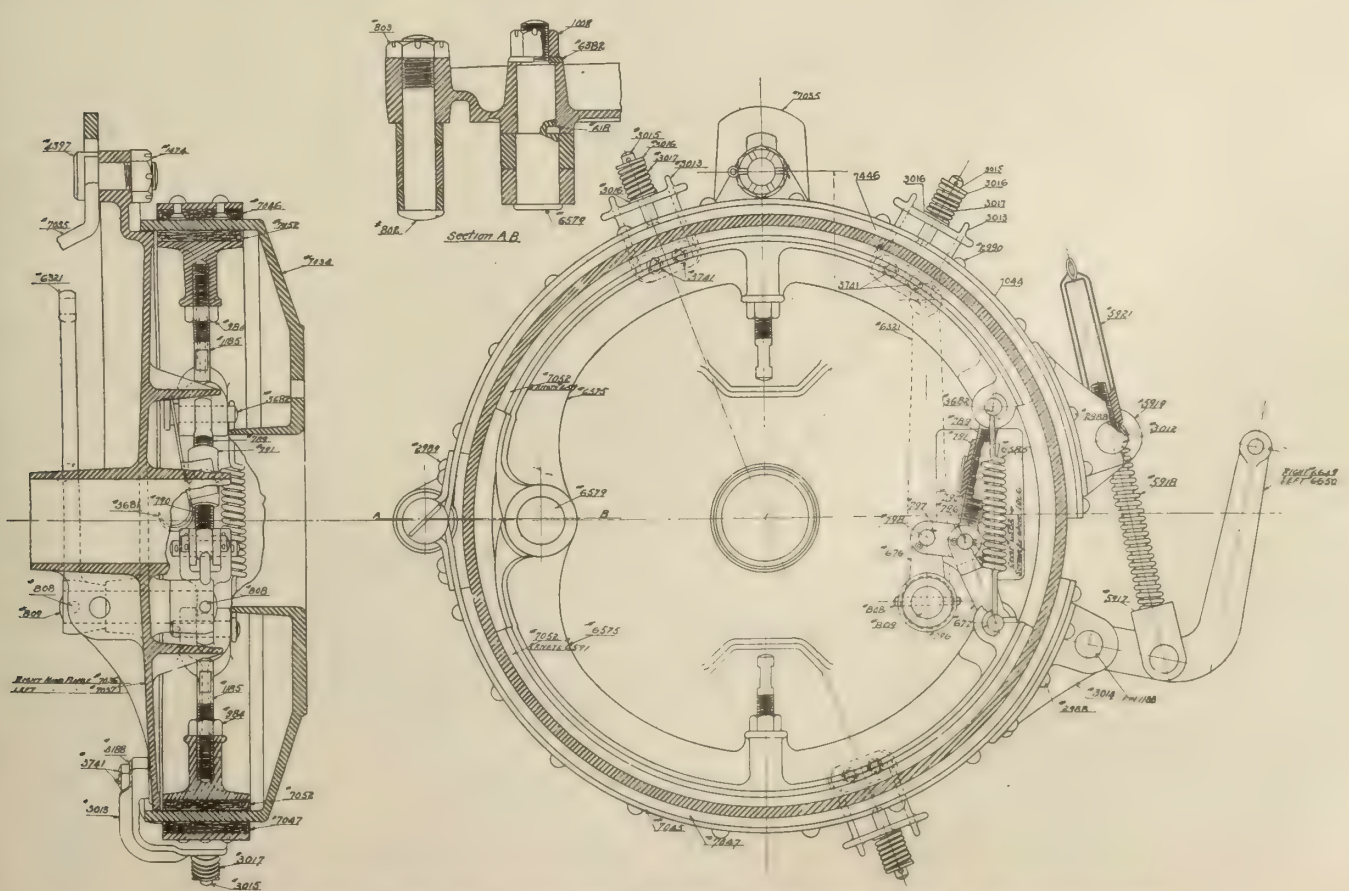

Fig. 1—An Effective Automatic Brake used on Russell Cars, Canada Cycle & Motor Co., Toronto.

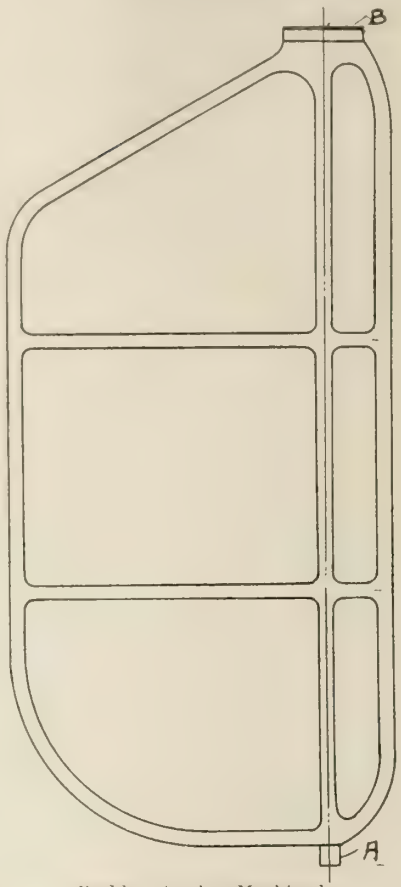
SHOP KINKS.

By M. E. D

Soft-soldering is not considered a very mechanical way of fastening machine parts, but it sometimes helps one out of a difficulty in a surprising manner. Over a year ago the writer had the job of repairing a lathe on which the main driving gear was loose on the spindle. The spindle was hollow, and so thin that it did not furnish a good support for the key. The gear, spindle, keyseat, and key were cleaned and carefully tinned. They were then heated hot enough to melt the solder, and were assembled. The lathe has been in hard service ever since, and the gear is still perfectly tight.

A very satisfactory extension drill may be had by taking a piece of iron or brass pipe, whose internal diameter equals that of the hole to be drilled, and with a crosspeen hammer make two dents directly opposite each other and about 1½ inches from one end. Into this pipe drive the twist drill, after having ground the end flat. This is a very good way of driving taps also.



In many small shops the screw machine and other tools are finish-ground on copper laps. These laps are about 10 inches in diameter by about ½ inch thick, and are mounted on the same spindle as the emery wheel. The lap is easily charged in the usual way by using a hardened steel roller and rolling the abrasive into it. Tools finish-sharpened in this way will do much better work, and will last much longer.

To drill a large hole clean from the start without jumping or chattering in the least, take a small piece of old rag or waste about the size of the end of the drill; place it under the point of the drill, and then drill through the rag or waste. This idea may be used to fa great advantage in countersinking work which requires a clean finish.

MACHINING RUDDER STEM.

The accompanying sketch is the steel frame of a large rudder being made for a boat 580 feet long, at the works of the Collingwood Shipbuilding Co., Collingwood, Ont. It is about 21 feet long, and nearly 10 feet wide, and when completed will be covered on both sides with boiler plate.

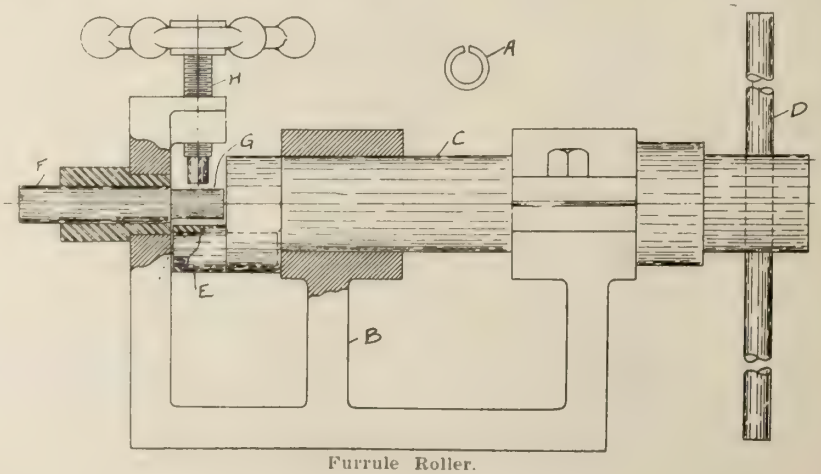
The machining of the bottom tip A of the rudder presented a problem, for the largest lathe in the shop had only an 18 ft. bed, and 18-in. swing, while a swing of at least 8 feet was necessary if the article was to be turned in the usual manner. The tip, itself, is only 5½ inches diameter by 5½ inches long. The difficulty was overcome as follows: The rudder was jacked up on its flat side on the carriage of the lathe. A cross tool was secured to the face plate, and after adjusting, the carriage feed was put on, feeding the work up onto it,

Rudder to be Machined.

thereby doing the work. A very neat and accurate job was produced in this way. The other end B was completed on the planer.

FERRULE ROLLER.

Chas. Barber & Sons, Meaford, Ont., have a neat little device, which they improvised recently to make the ferrules shown at A in the accompanying sketch. Large numbers of these are required as spacers in the guard racks made for their turbine installations.



The device consists of a body, B as shown. The shaft C, has a long handle D on the end for twisting, while the other end is formed as a crank with the desired throw. The crank pin has a hardened steel roller E on it. In the same line as the shaft is pin F, the inner end G being of the desired size of the inside of the ferrule. H is a clamping screw.

The stock, 1"x⅛" band iron, is cut the desired length, and one end of the piece placed between clamp H and pin G, after the shaft C has been turned to its highest position, the roller being thus over the ferrule blank. After clamping H, shaft C is revolved, the roller E bending the stock to the shape of the pin G. Pin F can then be withdrawn, this action removing the ferrule, leaving ready for the next. A boy can produce over a thousand in a day.

INSERTED CUTTER TAPS AND DIES

The uses to which high-speed steel has been put are numerous, in the metal working industries especially. Following the trend of development, Robt. Dryden, toolmaker for Sheldons' Ltd., Galt, has gotten out for use in the works, the tap and die shown in Figs. 1 and 2 respectively, wherein a minimum of high-speed steel has been made to do maximum duty.

The tap shown in Fig. 1 consists essentially of a machinery steel body A, on which the collar D is turned, and which has the four longtitudinal flutes as shown, the flute passing down through collar D as well as into the main part of the body. The split collar C is threaded corresponding to the thread of the tap, and can be tightened down by the side set screws. This collar, being faced off squarely, bears against the collar D on the body, and holds the chasers in alignment, and prevents cross-threads. Heavy working does not tend to put them out of position, but the reverse. The chasers are made in a solid arbor, into slots in which, they are tapped, eight at a time. It will be noticed that the slots in body A are so made that the cutting face is perpendicular. In order to back off the chasers, the grooves in the cutting arbor, are

Furrule Roller.

off-set slightly, so that the back is cut deeper than the front, so no backing-off attachment to the lathe is necessary.

Fig. 2 shows the inserted cutter prin-

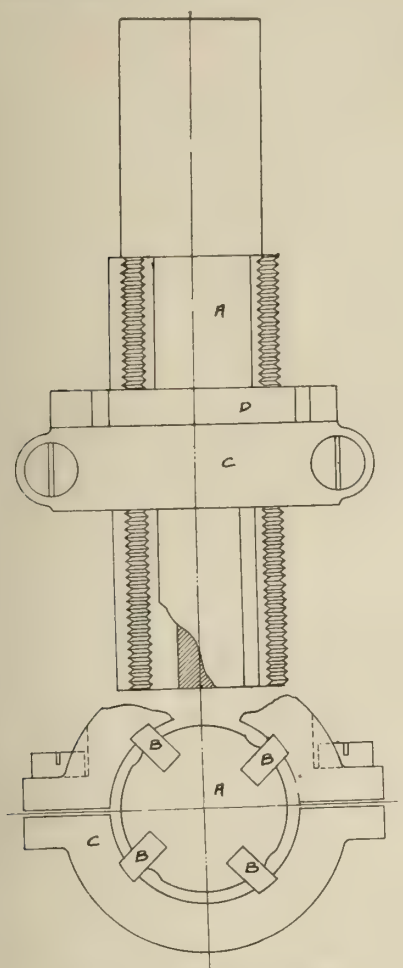


Fig. 1—Inserted Cutter Tap.

ciple applied to a die used for threading pipe plugs, etc. As before, the body A is soft steel, with high-speed steel

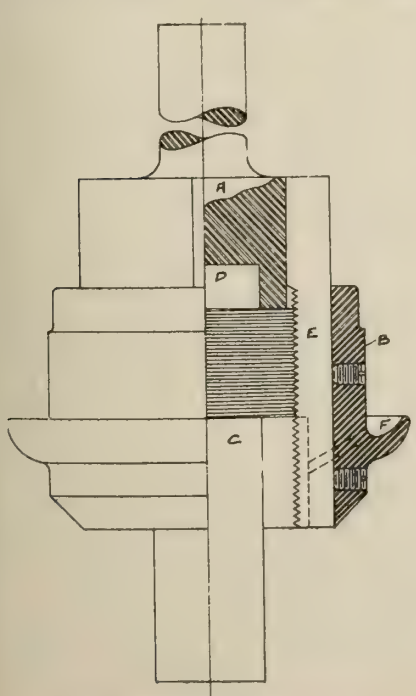

Fig. 2 Inserted Cutter Die.

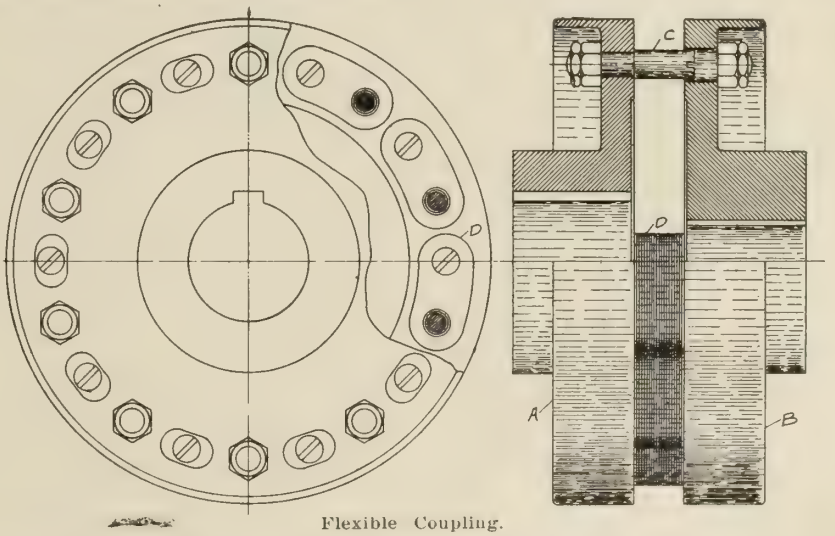


chasers E, held in position by collar B. To keep the alignment, a centre pin C is threaded, and has a tip D which centrally locates both chasers E, and pin C. Set screws in collar B adjust the chasers in, as desired.

One of the noticeable features is the method of lubrication. An annular channel F in collar B has several holes leading down from it to the face of the chasers, feeding the cutting fluid down on the cutting edges at all times.

The really valuable feature about both tap and die, is the longevity, for both will last an indefinite period. In all thread cutting tools, it is at the tip that the heaviest cutting occurs, causing the greatest wear at that point. In these inserted chaser tools, the tips can be ground off, and the chasers lowered a tooth, making them as good as new.

FLEXIBLE COUPLING.

The accompanying sketch is of a flexible coupling used by the Canada Gas Power and Producer Co., Barrie, Ont.,

Flexible Coupling.

for direct-connecting their gas engines to generators.

The coupling A is attached directly to the crank shaft, while B is on the generator shaft. It will be noticed that the arrangement consists of these two couplings, with pins, such as that shown at C, projecting inward, alternately from each one. For example, pin C, projects from A, and is free in a larger elongated hole in B, so that B may move up or down, etc., within limits, without fouling A. The next pin projects from B into A, and so on. Between these pins are leather links D, through which A drives B. This has proved to be an excellent coupling.

HOLDING LEATHER ON IRON PULLEYS.

By R. F. Williams.

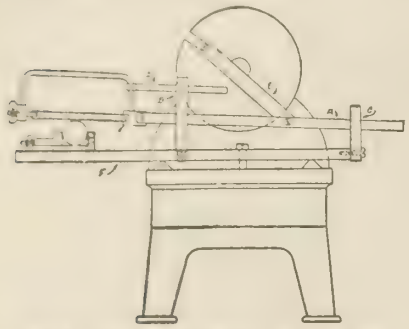
First soak twelve ounces of good glue in cold water. Put four ounces of boiled oil and four ounces of turpentine into the glue pot, and in this dissolve three ounces of resin. When the resin is dissolved, add the glue. The resin and glue should be well stirred while dissolving.

Before applying the leather cover to a pulley have it warm and dry, and scrape off all matter that may have accumulated on its face. Then with a swab, apply muriatic acid (full strength) to all parts of the face of the pulley. When dry, wipe gently with waste. Cut leather lengthwise of hide, and a little wider than the face of the pulley. Have the cement melted in the glue pot, apply it across the face of the pulley, with a brush, for about six or eight inches, lay on the end of leather and rub it down hard with the corner of a piece of wood. Fold back the leather and continue to apply cement until the pulley is covered. Two thicknesses of leather are used. Make the first thickness a butt joint, and the last a scarf or lap joint of about three or four inches long. Make the laps on the driven pulleys the way they should run, and on the drivers the opposite way. Pulleys should be cleaned by holding a piece of coarse sand paper against them.

HACK-SAW ATTACHMENT FOR LATHES.

By H. D. Chapman.

The accompanying drawing shows the way in which a hack-saw can be attached to a lathe. This will be found very handy about a small shop, and is inexpensive and simple in its construction. The device is so constructed that it can be easily put on and taken off the lathe.



The saw and its parts are mounted on a 1-inch thick by 8-inch wide cast iron slab; this makes the device easy to use on any lathe. The device consists of slide bar A, and two supports on each end, B and C, which are to guide the bar

A, the bar D is to brace the saw frame and to keep it from turning.

The slide is a flat piece of machine steel 5-16 inch thick and 2 inches wide; the length is about 4 feet, or to suit the stroke. A hole is drilled in the slide bar A for a 5-16 inch bolt. This is to hold the connecting rod E.

The supports B and C are made of 1-inch square stock. The support B has an end turned and threaded to suit a ½-inch tapped hole which is in the cast iron base F. The support C is bolted to the outer end of base, as shown. Each support has a 5-16 in. slot cut through the center, so as to allow a neat sliding fit to slide bar A.

The guide D is made of 5-16-inch by 1-inch machine steel. One end of guide

Hack Saw Attachment for Lathes.

is bolted to saw frame, allowing the other end to slide through support B, thus preventing the saw from having any wabble.

The connecting rod E is a strip of 5-16 in. flat steel about 2 inches wide and of a length to suit the saw frame. The connecting rod is also bolted to the face plate of the lathe, as shown in the cut, and can be adjusted in the slot of the face plate; this adjustment will accommodate the length of the saw.

The saw frame is made of machine steel, and the saw is made tight in the frame by means of a thumb-screw, as shown at the outer end of the frame.

An ordinary quelline vise is clamped to the base plate; this holds the stock while cutting off. This back-saw fixture is clamped to the shears of the lathe, as shown, and is held in position with a [illegible] bolt.—Scientific American.

Correspondence

Comments on articles appearing in Canadian Machinery will be cheerfully welcomed and letters containing useful ideas will be paid for.

Information regarding manufacturers of various lines, with their addresses will be supplied either through these columns or by letter, on request. Address letters to Canadian Machinery, 143-149 University Ave., Toronto.—Editor.

Tapping Hole Straight.

One of the questions asked a C.P.R. apprentice on a recent examination was: How can you tell whether a tap is going in straight or not, if the hole being tapped passed through the centre of a sphere? Perhaps readers of Canadian Machinery would have some ideas.—Reader.

Bolt Hole Facing Tool.

In the article "A Day's Ramble Through the M.C.R. Shops at St. Thomas," December issue, 1910, a description is given on page 39 of a Bolt Hole Facing Tool shown in the attached drawing, Fig. 1. The article states, "In

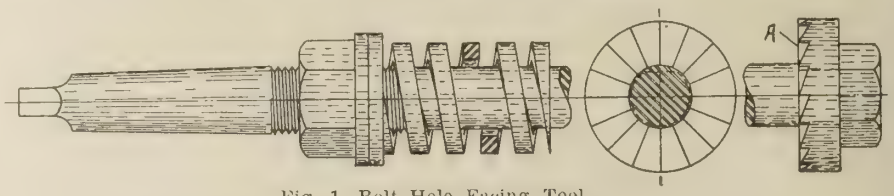


Fig. 1—Bolt Hole Facing Tool.

place of being keyed in the usual manner, the centre hole is bored flat on one side, and the bar itself flattened to correspond. Will you kindly explain how the cutter is "bored flat?"—Novice.

The hole in the cutter blank which is made of high speed steel, is first drilled with a 1 in. drill. The blank is then

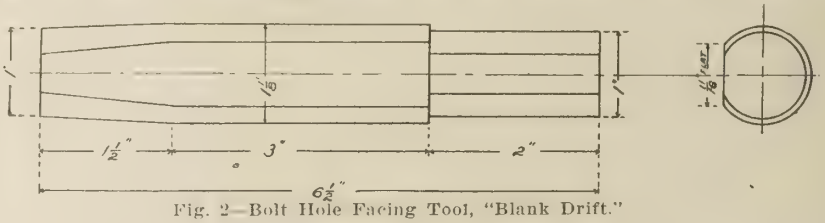

Fig. 2—Bolt Hole Facing Tool, "Blank Drift."

heated and the drift shown in Fig. 2 is driven through, thus leaving a flat side in the hole. The blank is then put on a mandrel and machined. This will no doubt satisfactorily explain the meaning intended by the words "bored flat."

WINNIPEG RAILWAY CLUB.

At a recent meeting of the Western Canada Railway Club, Winnipeg, S. A. Gidlow, general secretary of St. John Ambulance Association, C.P.R., Montreal, read a paper on "First Aid to the Injured." There were several practical demonstrations of ways of rendering "first and." These, which were superintended by J. T. Warde, G. D. Lockhart and Dr. Moorehead, showed methods of immediate treatment of: a compound fracture of the thigh; a broken collar-bone and fracture of the forearm, such as would likely follow a street car accident; and hemorrhage in different parts of the body. Also there was illustrated the right way to lift and carry a wounded man, and the Schaffer, Labord and Sylvester methods of inducing respiration.

Mr. Gidlow, in his lecture, pointed out in the commencement that a life might often be saved by the possession of a little intelligent, first-aid knowledge on the part of the by-stander. Illustrating his argument by little narratives of real accidents, Mr. Gidlow proceeded:

"The case of possible death by drowning demands special attention. Ignorant and careless handling of the supposed victim by drowning has often unwittingly completed the work of suffocation by immersion, and one can realize what this means in this country, where an average of seven hundred drowning accidents occur every year.

"First aid is a branch of work entirely different from that of the surgeon. It is special, and differs from the special training which every student receives. The medical student is taught to use all the best and most approved methods, while the first aid student is taught to use whatever is nearest to hand in the most scientific way possible. He must make a bandage out of a neck-tie or a handkerchief. He must improvise a tourniquet from a belt or a brace; for splints he must utilize a stick, a rifle, an umbrella or folded newspapers, and construct a stretcher out of a couple of broom handles and coats."

Mr. Gidlow explained the course of instruction in detail. The first three lectures dealt respectively with the bones, circulation and nervous system; and the fourth and fifth with methods of rendering first aid and of carrying the injured. As soon as the lectures were finished, the men were taken in hand by one of the company's ambulance instructors, and taught the practical work. Test questions were put to the classes before they were allowed to go up for examination.

In conclusion Mr. Gidlow told of the classes organized along the different divisions of the C.P.R., totalling 51 classes and consisting of 1,607 men.

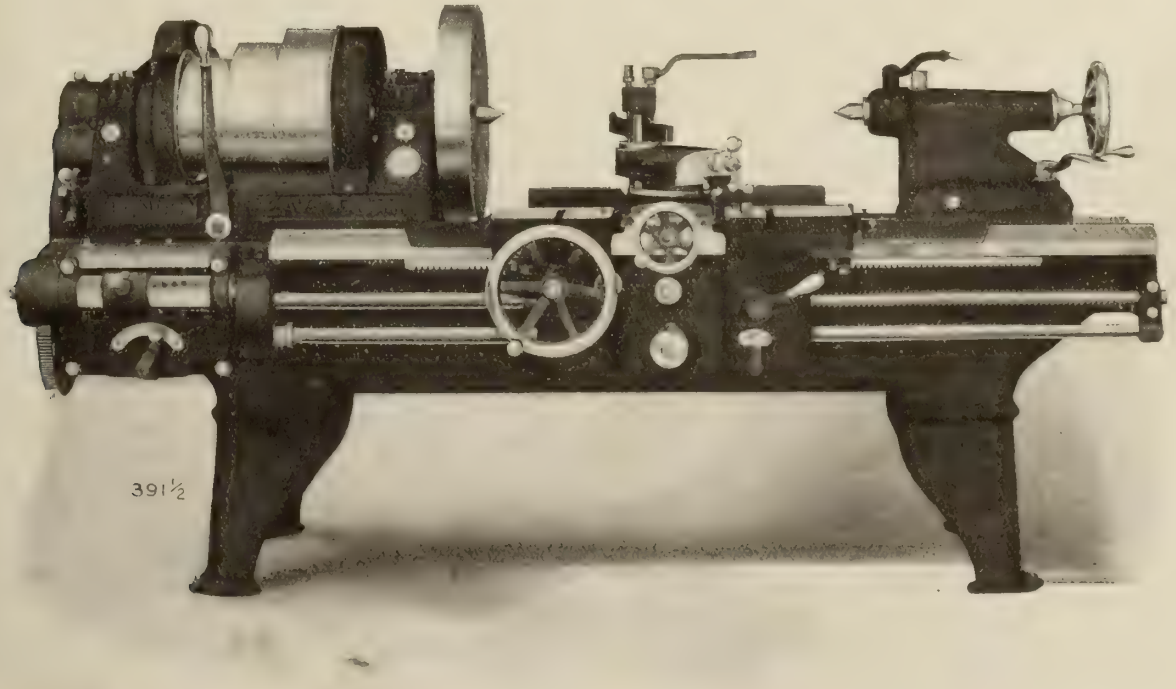
DEVELOPMENTS IN MACHINERY

New Machinery for Machine Shop, Foundry, Pattern Shop, Planing Mill; New Engines, Boilers, Electrical Machinery, Transmission Devices.

HEAVY DUTY ENGINE LATHE.

The accompanying illustration shows a general view and details of a 21 inch heavy-duty engine lathe recently placed on the market. This is one size of a line of lathes of the same type, including 17, 19, 21, 25, 27, 30 and 33 inch. lathes. The principle on which these machines have been designed has been to furnish a tool capable of taking a given cut and removing a given number of cubic inches of metal per minute. The 21 inch lathe shown is capable of taking a cut $^1_4$ inch. deep with a feed of 1-6 inch at a cutting speed of 65 feet per minute, in 50-point carbon steel. This is equal to removing 32 cubic inches of metal per minute.

The head stock is of the LeBlond improved drop brace pattern and is securely fastened to the bed with bolts of large size. The three-step cone pulley in conjunction with the double friction back gears and a two-speed counter shaft, provide in all, eighteen changes of spindle speeds, covering a range carefully selected for the purpose of the machine. The spindle is hollow and made of high carbon hammered steel, and is hardened and ground at the front and rear journals. These latter are carried in cast iron boxes scraped to a good bearing fit. This type of bearing the builders consider preferable because it does not require intricate oiling devices with continual attention on part of the operator; yet the lubrication is well taken care of. The bearing standards are cored out to form large oil chambers which are filled from the front of the lathe; from these the oil is fed to the bearings by means of felt pads. This construction eliminates all possibility of grit and dirt entering the bearings, and reduces the attention required to filling the oil receptacle once a week.



The tail stock is of massive design with a bearing of ample length on the bed. The tail-spindle barrel is designed in such a manner as to give the maximum length of bearing combined with long travel. Screws are provided for setting over the tail-stock for taper work, the base being graduated so that this setting can be easily accomplished.

A new departure has been followed in the design af the bed. The tail-stock slides on a V of the usual proportions on the rear way, and on a flat surface in the front. The carriage travels on a flat surface in the back, as shown, and is held down in the back by a flat gib. The front of the carriage slides on a guide of different shape from that usually found in engine lathes. This guide, as shown, is V shaped, but is machined at an angle of 15 degrees on the front side, and 70 degrees on the back, making the total included angle 95 degrees.

The carriage is held in alignment on a scraped surface on the front of the bed by taper gibs at both end bearings. This construction together with the 70-degree angle on the back of the V overcomes any tendency of the carriage to climb the ways when the lathe is engaged on heavy work. The gibs are tongued in position in the carriage, and in combination with the special construction of the V, they automatically compensate for the wear; this makes it unnecessary to give any attention to the adjustment of the gibs. Wipers are provided, fitted with felt pads, which in addition to wiping off chips and grit from the sliding surfaces also provides for automatic oiling of the ways.

The lathe spindle is set back a certain distance (in this size of lathe, two inches) from the centre of the shears, which construction not only provides for an increased swing over the carriage, but at the same time permits the machine to be used at full swing without the tool overhanging the bed, a construction which adds greatly to the rigidity of the machine when turning work of large diameters.

The apron is constructed of a one-piece box section casting with all gears

One of a New Line of Lathes Manufactured by the London Machine Tool Co., Hamilton.

and studs supported at both ends. The apron has a wide bearing on the carriage, is held in position by four bolts, and is fitted to the carriage by means of a tongue. The single box section form of the apron, it is stated by the manufacturers, does away with the necessity of an auxiliary support at the lower end of the apron, and overcomes the difficulty of uneven wear between such lower slides and the V on the top of the bed.

The longitudinal and cross feeds are operated by a single friction, which, in addition to being of large diameter, is so placed in regard to the gearing, that it has but a light duty to perform.

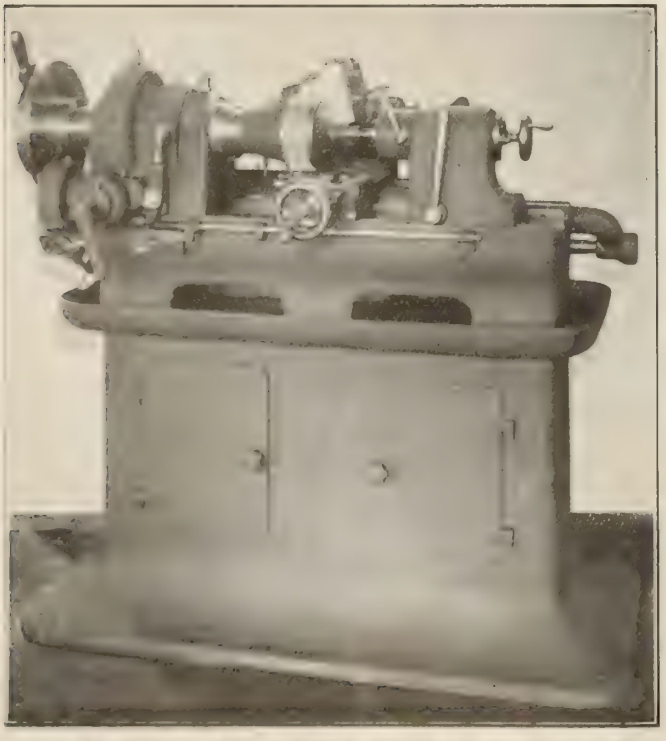
Nine changes of speed for the lead-screw are obtained by means of the cone of gears and the tumbler. The tumbler gear is supported on a cylindrical bearing, and is securely locked in position by the plunger in the change handle. This construction is the same as has been used on the LeBlond lathes for some time. The nine changes mentioned above are quadrupled by the addition of a sliding gear transmission. The gears of this sliding transmission are operated by the lower lever. This construction permits of the use of a speed or index plate which reads directly, and from which the operator can see at a glance the position of the levers required for any desired speed. The changes can be made while the lathe is running under the heaviest cut. The gears in the gear box as well as all other feed gears are made from drop-forged steel blanks. The feed rod is driven by the same mechanism by means of gears connecting it with the lead-screw, the range of feed being from 4 to 120 per inch. The changes for the lead screw provided by the gear box are thirty-six in number, ranging from 1 to 30 threads per inch.

The feed box is connected to the spindle by means of gears, the intermediate one of which is mounted on a quadrant, which permits the use of compound gearing at this point if required, for cutting special or metric threads with a standard English pitch lead-screw. A metric pitch lead-screw can also be supplied, in which case the gearing arrangement permits of cutting English pitch threads with this screw, by using compound gearing in the same manner.

These lathes are manufactured by the London Machine Tool Co., Hamilton, who have arranged with the R. K. LeBlonde Machine Tool Co., for the manufacture of their lathes in Canada. These are made on exactly the same lines as those built in the United States.

SPIRAL GEAR CUTTING.

The illustration shows a Pratt & Whitney 6 x 14-inch thread milling machine arranged for the cutting of spiral gears. The relation between the inner and outer spindle by means of which indexing is accomplished, is controlled directly by the index plate and pawl. The quick return device which is very conveniently actuated by a crank located at the front of the machine is very rapid in operation.



The machine is provided with precision lead and cross feed screws. Micrometer dial and positive adjustable stop give very accurate control of cutter head. One of the strong points of the thread milling machine is the locating of the cutter in a manner to prevent chip interference, which makes possible exceptionally fast feed without sacrificing quality of work. Three cutter speeds are provided. Eighteen carriage feeds for each speed of the cutter are instantly obtained by means of a geared feed box.

The machine and attachments have been placed on the market by Pratt & Whitney, Hartford, Conn.

INTERNAL THREAD MILLING.

The illustration shows a recently developed attachment for the milling of internal threads on the Pratt & Whitney thread milling machine. The cutter head, which is of rigid construction throughout, is made a complete unit and may be readily accommodated to the regular carriage. Its proper relation with the carriage is maintained by means of long dovetail bearings and a taper gib which may be readily adjusted for wear. The cutter head proper is so mounted that the necessary swiveling action for proper cutter clearance is obtained without disturbing the central relation of cutter and work, accurate graduations being provided for this purpose. The cutter head when set to the required angle is securely clamped to its seat by means of powerful bolts which makes it equal to a solid member in points of rigidity.

The cutter spindle which is made of tool steel is hardened, ground and lapped. It is provided with a taper

Pratt & Whiting Thread Milling Machine for Spiral Gear Cutting

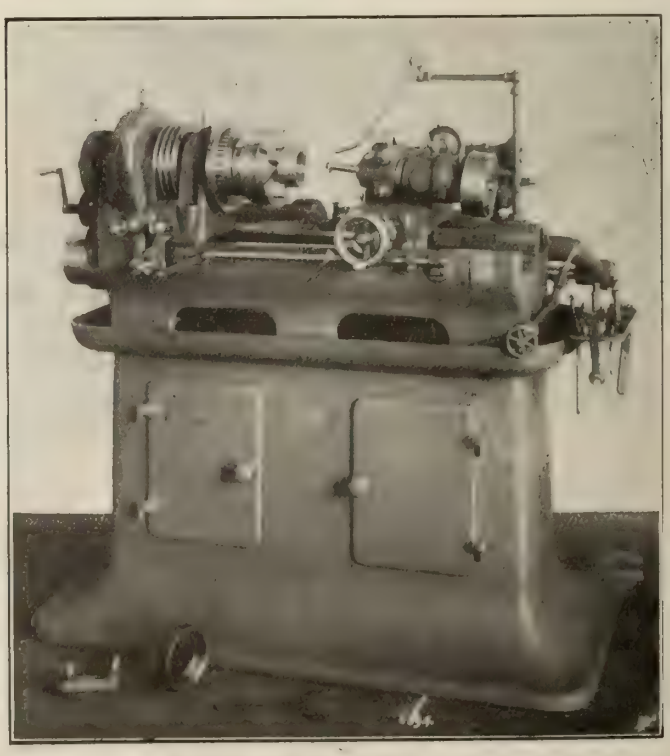


Fig. 1.—Pratt & Whiting Thread Milling Machine for Internal Thread Milling.

hole for the reception of the various cutter arbors, a drawback bolt being provided for holding the arbors in place. The bronze sleeve or box in which the spindle runs is mounted in the head in a manner to permit the longitudinal adjustment of the spindle,

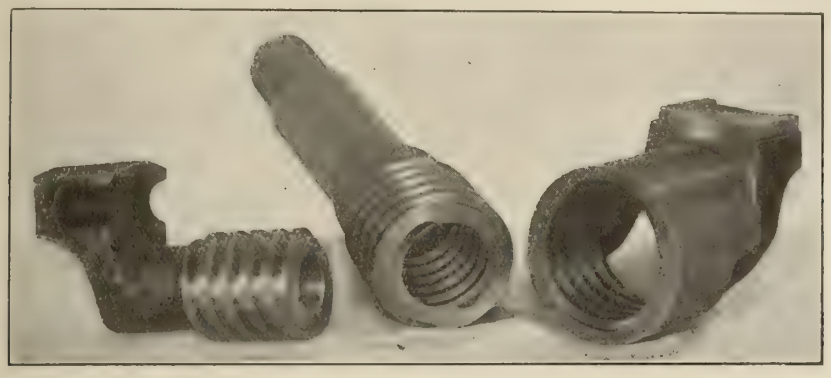

Fig. 2—Examples of Intricate Milling.

which is very convenient in re-setting the cutter to a previously cut thread. The cutter spindle is driven directly from the main driving shaft by means of gearing. Backlash in the driving gears which would tend towards the vibrating or chattering of the cutter, has been eliminated by the introduction of a fly-wheel. This fly-wheel is mounted in bearings independent of the spindle, yet in a manner to obtain the desired result very effectively.

A feature of the thread milling machine is the accurate and positive control of the cutter head obtained by means of the micrometer dial and positive adjustable stop. The simple and uniquely constructed stop which permits the withdrawing of the cutter from the work and accurately returning same to the exact previous depth, has proven especially valuable on internal work.

The cutter is provided with three speeds by means of a three-step cone. Eighteen carriage feeds are obtainable for each cutter speed through a gear box.

The machine may be arranged for the cutting of either single or multiple threads. When arranged for multiple threading, as shown in the illustration, the work-holding appliance is carried on the inner spindle, the outer spindle being provided with a very accurate index ring by means of which any multiple of thread desired may be cut. The index ring is very large in diameter in proportion to the work operated upon, therefore the tendency to inaccuracy is reduced to the minimum.

While the design of the spindle readily lends itself to the accommodation of the holding appliances necessary for the various classe of work, the step chuck and closer, as shown in place on the machine, has proven exceptionally efficient for work within its range. This step chuck, as will be noted, is provided with adjustable jaws, which are independent of the closing mechanism and when once set to the desired diameter or contour will hold the work rigidly and true. It is rapidly and conveniently operated by a drawback rod from the back of the spindle.

The attachment, as regularly made, is suitable for the threading of holes from about 1½ inches to 6 inches in diameter. It is equally well suited for single or multiple threads, either right or left hand. The machine may also be readily adapted for work out of the ordinary, a striking example of which is the device shown in the illustration.

The machine and attachments have been placed on the market by Pratt & Whitney, Hartford, Conn.

UNIVERSAL WOOD GEAR CUTTING MACHINE.

A new gear cutting machine has been designed and placed upon the market by the Newark Gear Cutting Machine Co., Newark, N.J., for the purpose of cutting the teeth of wood gears for patterns, especially spiral or helical gears. There is a wide field of work requiring heavy cast tooth "herring bone" or double helical gears, and such gears can be cast solid, from patterns cut on this machine. The pattern is in such case made in two pieces, one right and one left hand; but the casting is of course solid.

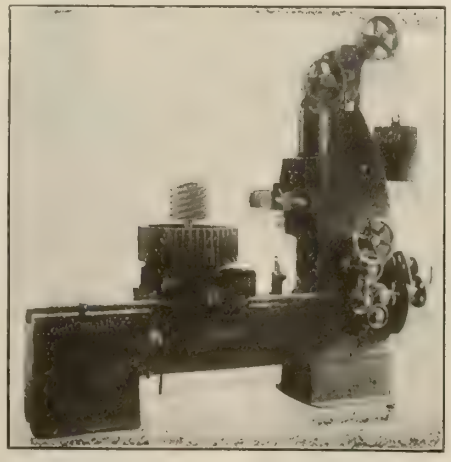

Fig. 1—Universal Wood Gear Cutting Machine for Cutting Spur Gear Patterns.

The machine has a capacity for spur gear patterns up to 8 feet diameter by 24 inch. face; and helical or "spiral" gear patterns up to 7 feet diameter by 24 inch. face. Any lead or angle of worm may be cut, as well as any numbers of threads; and any lead or angle of helical gear may also be cut. The range of pitches which the machine is capable of cutting is of course very large. By using fly cutters, all pitches ranging from 1 inch. circular up to 7 inch circular can be easily taken care of, and of course heavier pitches can also be cut by using regular rotary gear cutters.

In this machine, the feed is obtained by means of a hand wheel, operating a screw, with ball thrust collars. This hand feed is used, so that the operator may feed very fast during the full cut,

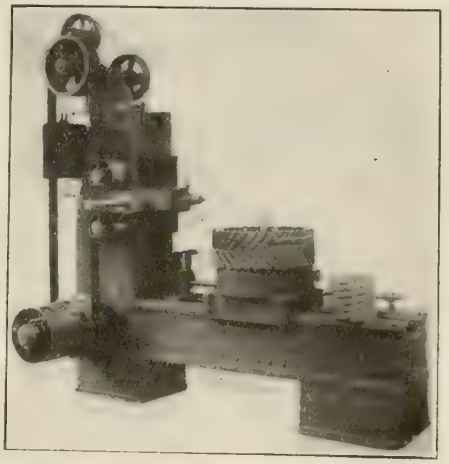

Fig. 2—Universal Wood Gear Cutting Machine for Cutting Helical Gears or Worms.

and may feed more slowly as the grain in the wood changes, or the cutter strikes a knot in the wood, or when the cutters come through at the end of the cut. After each tooth is cut the cutter carriage is returned to start a new cut, and the blank is indexed by the hand crank. A counterbalance serves to equalize the weight of the carriage.

The indexing is obtained by means of change gears. The operator makes one or more even turns of the crank, according to the index furnished.

All numbers of teeth can be cut, up to 100; and all from 100 up to 450, excepting prime numbers above 100, and a wide range of numbers above 450 can also be cut. When any unusual number is required, this can be arranged for, by means of an extra change gear.

In operation, the wooden pattern blank is mounted upon the work arbor, or upon the face plate direct. Blocks of

wood may also be cut on this machine, for use in gear tooth molding machines. A rim support is provided for taking the thrust of the cut, in large gears.

The face plate is solid with the dividing worm wheel, which wheel is made in two sections and generated in place, to secure accuracy. The dividing worm may be adjusted out of mesh with the wheel, to permit the blank to be rotated by hand. The dividing worm is also provided with adjustment for use in resetting, or in taking side cuts.

A complete guard protects the worm and wheel from dust and dirt.

The work head is adjusted on the bed, to take care of the various diameters to be cut, the adjustment being obtained by means of screw, with dial graduated to read to thousandths of an inch.

A noticeable feature of this machine, is the simple method of driving, as shown in Fig. 2, by means of an endless belt. The machine itself is driven by means of a tight and loose pulley arrangement on the machine; the pulleys running upon a rigid sleeve, and not upon the shaft, thus relieving the shaft of all strain of the belt pull, and eliminating the possibility of the machine starting up accidentally.

The cutters used on the machine, for heavy pitches, are shown in the illustrations. When cutting spur gear patterns, a formed fly cutter is used, mounted upon the spindle as shown in Fig. 1. This spindle makes 3200 revolutions per minute. When cutting helical gears or worms, an endmill form of fly cutter is used, mounted upon the endmill attachment shown in Fig. 2, making 4200 revolutions per minute. The spindles are of high carbon machinery steel, accurately ground, and run in phosphor bronze bearings.

Although the machine is designed for cutting wood, yet the design generally and the construction show distribution of the metal, with deep bed and box form of construction. This eliminates the tendency to vibration which would otherwise result from this class of work. The machine is very rapid in operation, as for example:—A wooden spur gear pattern, 10 teeth, 3 inch. circular pitch, 8 inch face, was cut in 30 minutes, cutting time. A motor drive can be readily provided for, as the machine pulley runs at constant speed.

AUTOMATIC CYLINDRICAL GRINDER.

The illustrations herewith show a new cylindrical automatic sizing grinder which has just been placed on the market by Pratt & Whitney, Hartford, Conn. The machine is designed for medium size work and has a capacity of 30 inches between centres, with a swing over bed of 4 inches, and can be adjusted to a maximum taper per foot of 2 inches.

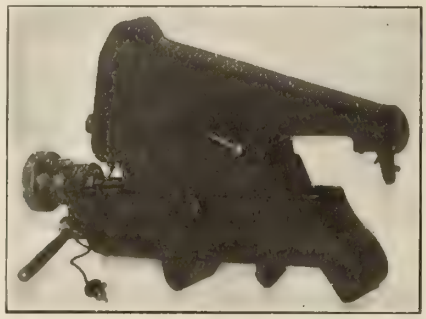

Fig. 3 Automatic Sizing Attachment.

The machine uses a 12-inch diameter wheel, with a face from ½ to 1¾ inches. Particular attention has been bestowed upon the table feeds and six changes have been provided for, any of which are immediately obtainable through a gear box and lever, the latter being located at the front of the machine, under the operator's hand. These feeds are independent of either wheel or work speeds. The reversing mechanism has been designed to effect reversal within 0.001 inch, a matter of considerable importance in grinding up to shoulders.

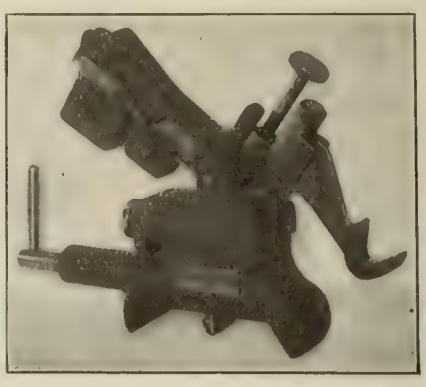

Fig. 4 Automatic Positive Feeding Back Rest.

The form of the table top has also received particular attention and is made with a flat top and angular sides, in order to insure accurate re re-location of attachments.

The most important recent improvement is the automatic sizing device as applied to this machine. This device when once set to the required diameter will automatically grind any number of pieces irrespective of the wear of the wheel.

In operation both roughing and finishing feeds are controlled and utilized, this not only greatly increases the production capacity of the machine but also insures far more accurate and uniform work than that resulting from ordinary micrometer measurement. A decided advantage made possible by this device is the ability of one workman to operate two machines to their maximum capacity without the slightest difficulty.

BELTS AND BELT DRIVES.*

By A. E. B.

BELTS and belt drives, the title of this article, will treat paticularly of the part played by leather belts as a means of transmission of power. Needless to say, their overwhelming, universal and undiminished use, stamps them as at once a subject of interest. One can hardly conceive of a factory without associating with it a belt drive, and our whole circle of readers is therefore expected to be benefited more or less. Such at least is hoped for.

Choice of Belt.

In the choice of a belt, the first consideration is that it be made from a

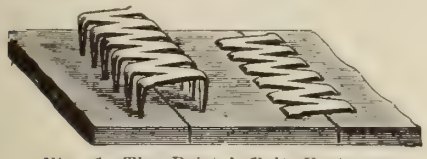

Fig. 1—The Bristol Belt Fastener.

good hide. All users are aware of the vast and varying range of quality offered at equally varying prices, and that it is no easy matter for the average purchasing agent to discern and choose to the best advantage his requirements. Some indicative opinion may be had by cutting a thin shaving from the samples offered, and tearing them between the fingers. Much belting is sold by weight, consequently unscrupulous dealers do not hesitate sometimes to impregnate the material with sugar and like substances, useless and worse than useless for any purpose, except increasing the seller's profits. The test already mentioned will enable even the unskilled to form an opinion as to how much of his purchase is leather, and how much simply weight-making material.

Lubrication and Stretch.

From the user's point of view, two things should be borne in mind. Dry leather is to be avoided and the belt should be thoroughly stretched.

Leather belts lose a good deal of their strength and nature unless impermeated with a certain amount of oil. Good quality cod oil is largely used for the purpose. This treatment gives pliability, ensures good driving qualities due to easy bedding of the belt on the pulley, and acts as a proof against the absorption of moisture.

*Part I. of the second article of the series of Power Transmission Equipment, Operation and Efficiency Subjects.

An ordinary belt thus lubricated, develops a stretching propensity, which is, of course, both troublesome and wasteful. For example, a new belt is put on to drive a machine, and in a few days it will probably have stretched some inches and be altogether too slack, necessitating a piece being cut out, wasted, and time taken to break and remake the joint.

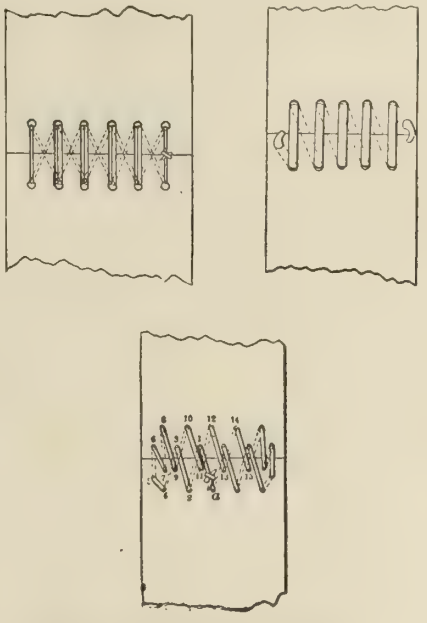

Fig. 2—Types of Laced Joints.

The problem, therefore, is to secure the admittedly advantageous features of "lubrication and stretch."

The solution is obvious—Stretch the belt fully before application. Many makers do put their belts through a stretching machine, and the belts benefit thereby; but the simple, rapid running through of a belt or parts of a belt is of little real use, seeing that the leather being in the same physical condition all the time, springs back to practically its original length as soon as the tension is let off.

A process of belt-stretching has, however, been introduced, having many commendable features and apparently successful beyond dispute. It is described briefly, as follows:

The hides from the tannery, prepared with a certain amount of moisture still in them, but with their oil dressing (in fact just in the condition in which most makers at once cut them up into belt strips) are taken to a special department fitted with special machinery. Each hide is placed over a strong frame and gradually stretched longitudinally until a 10 per cent. increase is reached; the lateral dimensions being meanwhile

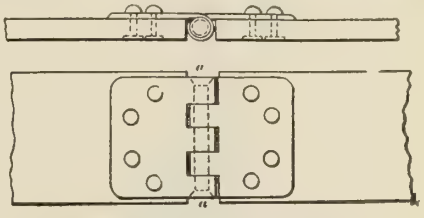

Fig. 4—Hinge Belt Fastener.

maintained by wedging. The required stretch having been obtained, the frame with its hide is taken away bodily and stored, sometimes for a period of several weeks, until all the moisture has evaporated. When released, there is little if any tendency to spring back to the original dimensions, the lubrication and pliability are maintained, and we have practically a stretchless butt of equal or even greater strength than before, and in ideal condition for cutting, jointing and the formation of a perfect belt.

The process involves considerable expense, and produces belts somewhat lighter, width for width, than unstretched belts, so that obviously higher prices per pound must be charged, but

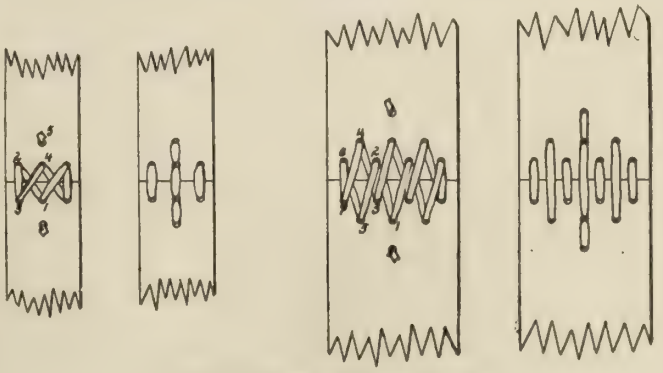

Fig. 3—Types of Laced Joints.

Fig. 5—The Jackson Belt Fastener.

the evidence goes to show that for lasting power, perfection of drive, and labor-saving, the belts are well worth their greater cost.

Strength of Belt.

The ultimate tensile strength of belting is not generally a factor in power transmission calculations. It varies from 2,000 to 5,000 pounds per square inch of net section in best quality leather belts, and may be reckoned at an average of say 3,500 pounds per square inch. This variation in ultimate strength is due not only to possible variation in the quality of the material, but to want of its homogeneity as well. Experiments go to show that strips of equal width and thickness taken from the same belting butt, gave breaking strains varying from 1,500 to 3,500 pounds per sq. inch.

Strength of Belt Joints.

The ultimate strength of a laced joint well put together should be taken at from 1,000 to 1,500 pounds per sq. inch, while that of a riveted joint may be taken as equal to one-half of the

Fig. 6. The Jackson Belt Fastener.

strength of the solid belt, 1,750 pounds per square inch. The working strength of the belt may, in practice, be taken as one-third the ultimate strength of the joint.

A series of tests of belts in actual use, showed the working strain to lie between 30 and 532 pounds per square inch. A commonly accepted working strain for best material of belt body, and substantial joint, is 320 pounds per sq. inch belt section, being 60 pounds per inch width for each 3-16 inch thickness, single belt. For double and treble belts the allowable strain would be 1.75 and 2.5 times that of single belts respectively. See belt creep.

Adhesion of Belts.

The motion transmitted by a belt is maintained solely by the frictional adhesion of the belt to the pulley rim surface. Belts do not communicate motion with precision on account of their liability to slip. With unequal diameter pulleys and an open belt, slippage will take place on the smallest pulley first, on account of the arc of contact being smaller. Crossing the belt makes the arc of contact the same on both pulleys.

A long horizontal belt increases the tension and arc of contact by its weight forming a curve between the pulleys. It should therefore drive from the under side. A belt running on a pulley on a vertical shaft requires stretching tightly because its weight lessens its contact. As a compensation, the belt

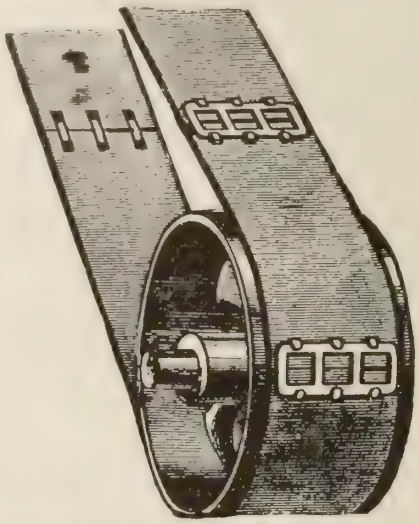

Fig. 7. Claw and Slide Belt Fastener.

should be broader than for a horizontal drive of equal power.

The adhesive grip of a belt is the same on cast iron pulleys, whether turned or not. It is greater however, on a wooden rim than on a cast iron rim.

Slippage of Belts.

A belt will slip just as readily on a pulley four feet in diameter as it will on a pulley two feet in diameter, provided the conditions of the faces of the pulleys, the arc of contact, the tension, and the number of feet the belt travels per minute, are the same in both cases.

A belt of a given width, and making any given number of feet per minute, will transmit as much power running on pulleys two feet in diameter, as it will on pulleys four feet in diameter, provided the arc of contact, tension, and conditions of pulley faces are the same in both cases.

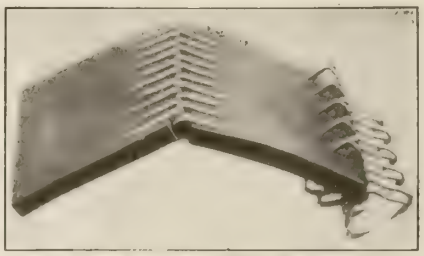

Fig. 8. Hinge Belt Fastener.

Causes of belt slippage are because they are overloaded, dirty, clogged, dried up and neglected. Slipping generates heat, and aggravates the trouble still further. The false, but common remedy of tightening up, or overtightening as it should properly be called, only results in straining the life out of the belt, increasing the coal consumption by increased bearing friction and disalignment of shafting.

It stands to reason that while slip may be prevented by undue tightening, this is not the right method to make the belt do its full duty justly. The added tension cannot help but increase journal friction, strain the shafting, increase the danger of hot boxes and worn bearings and increase the number of delays due to sudden belt failures, the prevention of which alone effects saving. No matter how well the bearings are lubricated, some of the pull on the belt is wasted in overcoming the added friction, and the capacity of the drive is reduced to the extent of overcoming this.

On the other hand, a belt that is kept

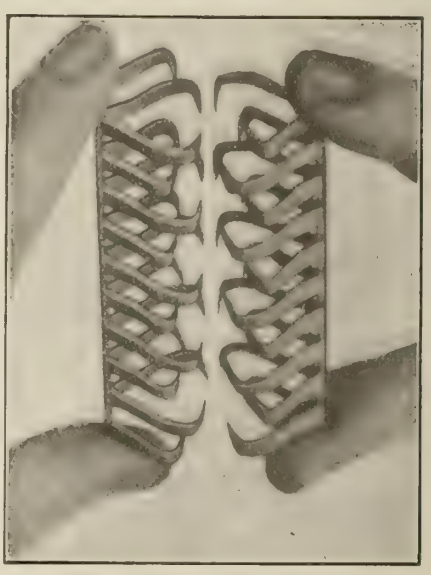

Fig. 9—Hinge Belt Fastener.

clean, mellow and otherwise in good condition throughout, by means of a suitable preservative, bends around the pulleys with less resistance and by reason also of a close conformity with unevenness of the pulley surface, can be eased or even run slack without danger of slip under full load. In fact, a belt that is properly filled and is of correct dimensions for its work, should break before slipping.

Preservation of Belting.

Engineers usually pay little attention to their belting except that which is giving immediate trouble, when as a matter of fact, proper treatment with a suitable preservative at regular intervals would greatly benefit all the belting. Not only would its life be prolonged, but by increasing the pliability and lubrication of the internal fibres, it would be kept softer, cling to the pulleys better, and run slack without slip, ensuring a saving of power that would much more than pay for the attention and cost of the preservative preparation. Anyone will understand this on considering that the natural in-

gredients of a leather, cotton, or camel's hair belt, manila or hemp driving rope, slowly dry out, and leave the contact surfaces hard. Unless something is added to replace these natural ingredients the belt or rope cannot be expected to grip the pulley close enough to transmit full load.

Creep of Belt.

By creep of belt is meant its stretching and contracting propensity as it passes over the driven and driving pulleys respectively, and is due to its inherent elasticity and nature of load. The tight side of the belt is under the greater strain, hence it stretches as it comes on the driver and contracts coming off. In a word, more belt length goes on to the driver than comes off it, and more comes off the driven pulley than goes on. The net result is that there is a continuous creep or shifting of the belt around the pulleys in a direction opposite to that in which the belt runs. Fig 10.

Belt creep in practice is usually kept within a one per cent. limit, and to make certain of its attainment, the working strain for best material belt body and substantial joint is taken at 40 pounds per inch width, single belt, with that for double and treble belts in the proportion already stated.

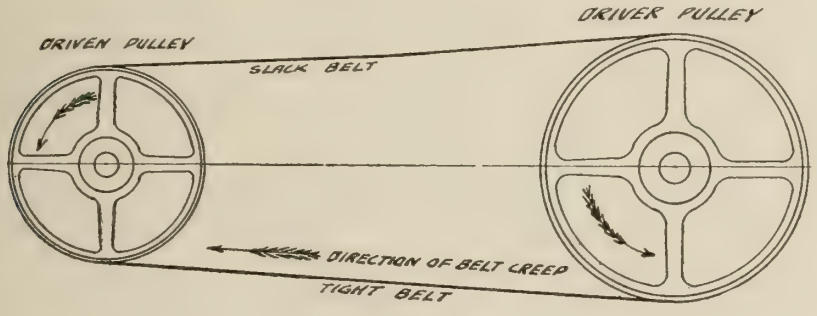

Fig. 10—Belt Drive.

Centrifugal Tension of Belts.

When a belt runs at a high velocity, centrifugal force produces a tension in addition to that existing when the belt is at rest or moving at a low velocity. This centrifugal tension diminishes the effective driving force.

Double belts are less pliable than single belts and the centrifugal force is greater, consequently the contact with the pulleys is less. Furthermore, the tension is seldom increased proportionately, and for these reasons, double belts should not be expected to transmit more than 8-5ths the power of single belts.

This power may be increased, however, by running two single belts on top of each other. Being thus more pliable they give better contact and increase may have a difficulty betimes in knowing just what to do, and have their back to the wall, they will be found efficient and satisfactory in operating results.

The power of belting is determined by the number of foot pounds which can be transmitted by one pulley to another, and is arrived at by multiplying the effective pull in pounds per inch of width, by belt width in inches and by belt speed in feet per minute; thereafter dividing by 33,000.

The effective pull or the force tending to turn the pulley is the difference in tension between the slack and driving sides of the belt, and is largely dependent on the arc of contact between the belt and the smaller pulley.

To find the effective pull it is necessary to determine the number of degrees in the arc of contact. This can be arrived at by multiplying the difference between the pulley diameters in inches by four and three quarters, dividing the product by the distance between the pulley centres in feet, and subtracting the quotient from 180 degrees.

Horse Power of Belting.

Users of belting are frequently misled as to the amount of work which should be expected of a good belt, with the result that it is put to an excessive strain and sent to the scrap heap in a short time, condemned as to quality.

This condition of affairs is due in large part to incorrect rules for calculating the power of belting.

These rules are in many cases wide apart in their results as are the poles, and the practice of them is so varied that hardly any two users adopt the same. In the face of this seeming utterly irreconcilable state of affairs, I make no pretension of pointing out where each errs, or of submitting a rule to which all others should give place.

The following explanation, however, of the considerations to be accounted and the rules accompanying, have been made the basis for numerous installations by the writer, and to those who

$$\text{Arc of contact} = 180 - \frac{(36-24)\times 4\frac{3}{4}}{18}$$

$$= 180 - \frac{12\times 4.75}{18}$$

$$= 180 - \frac{57}{18}$$

$$= 180 - 3.16$$

$$= 176.84 \text{ degrees.}$$

$$\text{Effective pull} = \frac{176.84\times 40}{180} = 39.29 \text{ lbs.}$$

$$\text{Horse power} = \frac{39.29\times 6\times 2000}{33000} = 14.29$$

Rules which take no notice of effective pull and known as empirical, have been likewise used by the writer to advantage, and are as follows:

$$\text{Single belts—horse power} = \frac{W\times V}{800}$$

$$\text{Double belts—horse power} = \frac{W\times V}{500}$$

W=width of belt in inches.

V=velocity in feet per minute=circumference of driving pulley in feet multiplied by revolutions per minute.

Example.—Taking belt width and velocity as in previous example we get

$$\text{Single belt horse power} = \frac{6\times 2000}{800} = 15$$

The result is practically the same in each case, but arrived at by a much simpler method in the latter case.

To get the horse-power that a double belt of the same width and velocity would transmit, the second formula would be used.

$$\text{Double belt horse-power} = \frac{6\times 2000}{500} = 24.$$

Figs. 1 to 9 illustrate some methods of belt jointing and a few of the specialties in common use.

WHAT IS SCIENTIFIC MANAGEMENT?

By G. C. K.

The question of "Scientific Management—What it is and What it will do," has been prominently brought before the mechanical men of America by the United States Interstate Commerce Commission. Expert testimony has been given by such men as H. K. Hathaway, of the Tabor Mfg. Co., manufacturers of molding machines; James M. Dodge chairman of the Link-Belt Co., Philadelphia; Henry R. Towne, president of the Yale & Towne Mfg. Co., Stamford, Conn., makers of Yale locks; Frank B. Gilbreth, New York; Henry L. Gantt; Harrington Emerson and Wm. Kent.

Wm. Kent sums up Business Management in a few lines. "Scientific management might be termed "applied common sense." It requires a man to do only that work for which he is best suited, but requires him to do that work at his greatest efficiency. It requires that he shall not do that work for which by training or environment he is unfitted and which someone else can do better than he. It requires that the conditions be made right for the greatest efficiency of the worker, this including not only the tools he works with, but his surroundings, his pay, and everything else which affects his work."

Andrew Carnegie stated some years ago: "Take away all our factories, our trade, our avenues of transportation, our money, leave me our organization and system, and in four years I shall have re-established myself." This, in brief, is what scientific management will do.

Passing of Rule o' Thumb Methods.

What it will do was given in an editorial in a recent issue of the New York Times. It states in a very concrete way what scientific management or system will do for any industry.

By rule o' thumb a man could unload two tons of pig iron an hour, for which his employer paid him 16 cents an hour. An observer, who had never handled a pound of pig iron, saw that the tracks in the foundry might be laid so that each bar need be carried not more than ten feet. By trial he saw that the average man unloading could move at a greater average speed. He saw that several of the physical movements used to transfer a bar from car to pile were unnecessary, consuming time and energy. In these three respects he established "units of efficiency," taking care, also, to provide a system of rest intervals to prevent fatigue. He then declared a standard of unloading pig iron at the rate of seven tons an hour to be easily practicable, and recommended a wage scale of 2.7 cents a ton, or 19 cents an hour, for the men who conformed to this standard. Under a sliding upward scale of wages, men were found willing and able to handle continuously ten tons an hour, for which service each received 27 cents. The increase in output was fivefold that under the rule o' thumb; the wages paid were seven-tenths greater, and the laborers were physically and financially better off.

"Gangs shoveled with the same shovel such different materials as coal, coke, iron ore, sand, and lime. A man who had not seen much shoveling done, but with trained powers of observation, determined that for each material a shovel which would hold 22½ pounds—a fair weight for the average laborer—should be of special size and shape. Then a set of necessary movements was devised with reference to physical leverages and speed. It was found, too, that a pile of lime or sand should be attacked at the top, and of coal at the bottom. Having fashioned the standard shovels, and devised the units of speed, movement, and weight, he found that the new method and a system of bonuses increased the efficiency of the shoveling gangs 150 per cent.

"For forty centuries the bricklayer stooped to pick up his bricks. The "efficiency engineer" devised platforms on jacks raised by boys to the level of the growing wall. Under the rule o' thumb the bricklayer for ages turned his brick any or all of three ways to find the face, tested the good bricks, picked up and threw down the defective ones, which had to be lowered from the height to which they had been raised, and turned his trowel to tap each good brick into the mortar. Boys now sort the bricks on the ground, piling the good ones face forward upon the platforms, and the brick sinks of its own weight into a new consistency of mortar. Bricklayers got $5 a day. Gilbreth enabled them to earn $6.80 a day, at the same time trebling their efficiency.

"Such methods kill rule o' thumb wherever introduced. They are not respecters of persons or of professions or of trades. They are usually introduced by outsiders—men who 'know nothing about the business.' "

Actual and Possible Savings.

In the December issue of Canadian Machinery the principles of scientific management applied to the repair and building of locomotives on the C. P. R. by Henry L. Gantt. These resulted in a saving of $65,000 per year. Harrington Emerson applying the priciples of scientific management to the Santa Fe railroad effected a saving of approximately $5,000,000 in three years. Such was shown by the testimony given before the Interstate Commerce Commission at Washington.

James M. Dodge pointed out the methods of management in the shops of the Link-Belt Co., Philadelphia, that made money. All work done in the shop is laid out for the workmen by a planning department in accordance with records based on accurate time studies of the fundamental operations of the job; the machine tools have all been standardized and their exact capacities are known; in the shop the work is supervised by functional foreman, each of whom attends to some feature of the work. By establishing a "system" the costs were reduced in the face of a rising labor and raw material market.

Some Pertinent Questions.

Writing to the Railway Age Gazette, E. T. Spidy, instructor Card Inspector, C. P. R. Angus shops asks the following pertinent questions. The foremen in various industries and railroad shops should carefully study them and strive to benefit by them. A study of them in detail will result in unprecedented savings and show "good management."

Is my piecework system in good condition—can I improve it in any way?

Have I machines that are overburdened or doing a class of work for which they are not suited?

In what conditions are the machines? Are they in a state of good repair?

Do any machines require re-speeding?

Am I using the best steel obtainable? Do I know what the best steel is?

Are my tool standards correct?

Do my men receive their tools in a satisfactory way?

How is the tool room stocked? Are there sufficient tools ready for delivery?

Do the men have trouble getting their work?

What kind of hoist service have the men at their machines for individual use?

Are the men provided with sufficient light?

Have you a proper belt-repair system?

Conclusion.

If managers, superintendents, master mechanics and foremen take the subject of Scientific Management seriously they will thank Louis D. Brandeis and the United States Interstate Commerce Commission for the valuable data which has been brought to light. Mr. Brandeis stated that the railroads of the United States were wasting $1,000,000 per day through lack of system. No doubt the railroads have done much towards scientific management and some industries have been wide awake, but there is still much to be done.

Scientific management when applied to the simple operation of loading a freight car with pig iron increased the performance of the individual from 12½ to 47 tons; when applied to shovelling coal it doubled or trebled the performance of the shoveller; when applied to the machine shop it developed, in certain operations, increases ranging from 400 to 1,800 per cent. This has been done in the face of the increased cost of labor and material. The principles are general in their application and where applied, valuable results will be obtained.

BUSINESS OPPORTUNITIES.

The C.P.R. have issued a second edition of their book on "Manufacturing and Business Opportunities in Western Canada," along the lines of the C.P.R. It is edited by John F. Sweeting, C.P.R. industrial agent, Winnipeg, and in addition to an index of stations, it contains an index to industrial requirements, facts in relation to the towns and cities of the West and tables of Western water powers. The following requirements for manufacturing concerns and power plants, are taken from this C.P.R. directory.

Agricultural Machinery—Fort William, Ont., and Winnipeg, Man.

Automobiles—Victoria, B.C.

Cement Plant—Southey, Lanigan, Weyburn, Macoun, Wilkie, Estevan, Francis, Outlook, Sask.; Edmonton, Bowden, Wetaskiwin, Crossfield, Penhold, Strathcona, Didsbury, Hardisty, Strome, Alberta; St. Boniface, Winnipeg, Man.; and Cranbrook, Kamloops, B.C.; Westfort, Ont.

Cold Storage—Saskatoon, Sask.

Can Factory—Victoria, B.C.

Engine Works—Stationary, Marine and Traction, Fort William, Ont.

Electrical Supplies — St. Boniface, Man.

Electric Lighting Plant — Holland, Souis, Pilot Mound, Rapid City, Man.; Swift Current, Lang, Lanigan, Elbow, Arcola, Sask.; Didsbury, Olds, Hardisty, Innisfail, Leduc, Granum, Alberta; and Port Moody, B.C.

Foundry—Saskatoon, Weyburn, Sask.; Camrose, Claresholm, Medicine Hat, Alberta, and Kamloops, Rossland, B.C.

Gasoline Engine Works—Portage la Prairie, Man.

Machine Shop — Saltcoats, Francis, Saskatoon, Strassburg, Estevan, Hawarden, St. Aldwyn, Perdue, Sask.; Shoal Lake, Glenboro, Rapid City, Morris, Man.; Wetaskiwin, Camrose, Amisk, Metiskow, Stirling, Alberta; and Armstrong, Rossland, B.C.

Motor Car Factory—Regina, Sask.

Nail Works—Fort William, Ont.; and Winnipeg, Man.

Planing Mill—Austin, Gimli, Man.; Weyburn, Sask.

Sash and Door Factory—Virden, Rapid City, Man.; Wapella, Arcola, Wilkie, Strassburg, Elbow, Sask.; Coleman, Alberta; and Fernie, Port Moody, Nicola, Enderby, Kitchener, B.C.

Saw Mills—Gimli, Man.

Smelting Works—Medicine Hat, Alberta.

Shingle Mills—Nakusp, B.C.

Wire Fence Factory—Calgary, Alberta

The G.T.R. Industrial Bureau announce the following openings for business along the line of the G.T.P. in Western Canada:—

Box Factory—Edmonton, Alta.

Brick Manufacturer — Lazare, Man.; Biggar, Waldron, Sask.

Carpenter Shop—Anoka, Otthon, Alta.

Foundry—Edmonton, Alta.

Societies and Personal

F. H. Sexton, director of technical education for Nova Scotia, is to accompany the Technical Education Commission on its visit to Europe.

* * *

A. J. Gaul, of Gaul & Girourard, Toronto, read a paper on "Diamond Mining in South Africa" before the Central Railway and Engineering Club on Jan. 17.

* * *

The closing of the works of the Canadian Fairbanks-Morse Co., Toronto, for a day, was a fitting tribute to the manager Percy C. Brooks, who recently lost his wife and three children in the burning of his home when he was in Chicago. The sympathy of Canadian Machinery and its readers, is extended to Mr. Brooks in his sad bereavement.

* * *

Walter J. Sadler, who for the past fifteen years has been connected with the firm of Sadler & Haworth, Montreal, manufacturers of leather belting, has been taken into partnership.

* * *

F. M. Brown, general purchasing agent of the Dominion Steel Corporation, has resigned to accept the position of vice-president and general manager of the Nova Scotia Car Works, the company that succeeds the Silliker Car Co.

* * *

The St. Thomas machinists will hold a ball on Feb. 16, in the Engineers' Hall. The following are the committees: Invitation committee, Stalker Booth, John H. Grey, Peter Erickson; music committee, W. E. Moore, Frank Clark; hall committee, Thos. Stone, John Lane; refreshment committee, Thos. Stone, W. E. Moore, J. H. Grey; chairman, J. Lane; secretary-treasurer, W. E. Moore.

* * *

Lake Superior Corporation.

Vice-President J. F. Taylor, of the Lake Superior Corporation, Sault Ste. Marie, has been appointed general manager and W. C. Franz has been made vice-president of the transportation interests of the corporation. Other changes include the promotion of C. H. L. Jones to the post of assistant secretary-treasurer, and that Consulting Engineer Ernst to general manager of the Algoma Steel Co., with C. E. Duncan as general superintendent.

* * *

Winnipeg Boilermakers.

Fort Garry Lodge 451, Brotherhood of Boilermakers, Winnipeg, held its annual smoking concert January 17, to which the C.P.R. were also invited. The chair was occupied by President J. Tumilson, and the programme which was contributed to by the best entertainers from both unions, was of very interesting character. Character songs and step dances were given by J. Crawford and J. Mugford, the other contributors including J. Hawthorne, W. Lawlor and J. Edwards.

At the recent annual meeting, the following officers were elected: J. Tumilson, president, re-elected; J. Handford, vice-president; J. Hume, financial and corresponding secretary; J. Tumilson, treasurer; J. Waddington, recording secretary; J. Hawthorne, inspector; R. Gardiner, guard; J. Handford, F. Magford and J. Tomes, trustees. The installation was conducted by J. Hume, past president.

CANADIAN MACHINERY AND MANUFACTURING NEWS

A monthly newspaper devoted to machinery and manufacturing interests mechanical and electrical trades, the foundry, technical progress, construction and improvement, and to all users of power developed from steam, gas, electricity, compressed air and water in Canada.

Vol. VII. February, 1911 No. 2

CANADIAN MACHINERY EDITORIAL INDEX.

At the close of the past year many requests came to us from subscribers of Canadian Machinery for an editorial index for use in binding their 1910 volume. In order that every subscriber may obtain the greatest use of his 1911 volume, we are numbering the editorial pages consecutively and at the end of the year, will issue a complete index of articles and authors, so that any article may easily be found by a reference to the index.

This is one of many steps forward which we contemplate taking and which will be announced from time to time. By means of these we hope to make Canadian Machinery of still greater use to our readers.

INCOMPETENCY AND INEFFICIENCY.

It seems that in the last analysis, the employer or responsible administrative head of a factory or corporation is he who determines the grade of efficiency of the undertaking.

We don't associate with an intelligent employer a stupid, ignorant official and administrative staff, but rather do we expect such a staff as will reflect his attributes.

The selection of men to fill the various subordinate appointments is not wholly a trial and error proposition, neither is it an evolution or "survival of the fittest." Definite, reliable, personal knowledge or experience of ability determines in large degree who shall fill the more responsible posts, and a corresponding line of action is again developed with regard to those further down the scale.

While it is possible to evolve men for positions, or have the position evolve as it were the man, and while such instances are of daily occurrence and necessarily so, it is inexpedient to operate from such a basis as a business principle.

We are accustomed these days to read and hear much about the cost of incompetence and inefficiency, and to see many more or less glaring spectacles of it, but what strikes one most forcibly about the two evils is their universality and existence in every walk of life. In the best and highest realms of human development and culture as well as in the lowest and ignorant, there is to be found incompetency, there is to be found inefficiency.

The question arises, can we minimise, escape from or cut out entirely this condition of things? It seems as though it were absolutely necessary to do so.

Escape from this dual curse, for such it is, does not of course imply that all men would be equally competent in any or every sphere of usefulness. The fault at the present time is that men don't fill their own individual niche to the best of their inborn and knowledge-nurtured ability, nor do they realize their intense, inherent possibilities. A keen discernment of one's proper sphere would do much to minimise that feature of incompetence and inefficiency which arises as a direct result of men operating in a wrong and unnatural department.

Being human, however, escape will be possible of only partial attainment, and we should not lose sight of this stern fundamental fact.

It is claimed that incompetency costs the city of Chicago one million dollars per day. John Wanamaker claims that incompetency costs his company twenty-five thousand dollars per day. Others again claim less or greater losses attributable to the same cause.

The basis of estimation is not stated, neither can we judge the standpoint of the estimator. To criticize and say there is certain loss, comes easy and is only wrong in degree, which at all events may be enough; but to charge the loss individually and in proper proportion and suggest a remedy, is neither easy nor pleasant if honestly and faithfully carried out. It is, however, the way to tackle the question properly, and most certain of remedial results.

Getting back to our starting point again, it will appear evident that the larger proportion of the loss is chargeable to the chief administrator, and he, if a factory owner, suffers in his returns just to that extent.

If it be the city of Chicago, the real administrators lose, to wit, the citizens. An inexorable law is therefore unfolded which metes out to all their share of punishment for neglect.

One thing must not be overlooked in this crusade against incompetency and inefficiency; the steady, certain real uplifting of mankind and its consequent change and raise of standard.

If Chicago by some means or other redeemed itself by saving that million dollars per day, and nobody will question its ability to do so if everyone did his or her own little part, if the employes of the Wanamaker company each added their little extra effort to what exists, if the "kick" that everyone makes and the losses claimed were satisfied, as they could easily be on the amounts specified, what then?

Would Chicago, John Wanamaker, you and I be satisfied? No, and why?

The realization of what was esteemed competency and efficiency, and which we prided ourselves in determining is not perfection as was thought.

We have much to be thankful for that the ideal will always keep ahead, and that the craving to reach to it

will still express the efforts made, as falling short through incompetence and inefficiency.

The standard of estimation will be rising all the time, as it has done and is, and will be found more exacting as it takes each time higher ground.

A scheme of education, not necessarily technical, which would dispose men to cultivate and use their intelligence in the selection of their proper sphere and the efficient filling of it, as a personal moral responsibility, while not ushering in the millennium, will obliterate to a great extent what are certainly at present monstrosities of incompetence and inefficiency.

MACHINERY MAINTENANCE SAVINGS.

At a recent meeting of the National Machine Tool Builders' Association, C. K. Lassiter, Mechanical Superintendent of the American Locomotive Co., read a paper on "The Design and Construction of Machine Tools from the User's Standpoint," in which he gave some excellent suggestions for the maintenance of equipment. By consistently carrying out a factory management system, giving specialized attention to the duties of caring for and maintaining equipment, large and almost inconceivable savings are made. By such a system, properly administered, the American Locomotive Co. have reduced the lost productive machine hours from 12 to 1¾ per cent. There are 9,000 machines in the plant. Formerly 1,000 were out of use continuously but now 100 machines is the average number out of service.

In the plant referred to, each department has an inspector who investigates the machinery for probable failures or for conditions which might cause accidents to employes. His findings are made out in the form of a report and immediate steps are taken to correct any condition which might render a machine idle. Where the design of the machine is at fault, it is strengthened or redesigned.

The following shows the working of the system as given by Mr. Lassiter :—

"In one of our shops, by referring to our reports, we found that 40 per cent. of the failures were due to negligence. We were able to reduce this item to 1¼ per cent. In another case we found that we were purchasing a certain machine from some of the machine tool builders, and there was an error in design which had existed for ten years on this machine, which was costing us something like $5,000 per year. We took the matter up with the machine tool builder and had the design changed. This charge was eliminated, which was like picking up so much money.

"We found that the maintenance on some machines which we had in service was so heavy that we could not afford to keep the machine in service, and we replaced them with modern tools. This also showed a decrease in maintenance."

Mr. Lassiter referred to the savings made by designing special machines :—

"Most of the tools which we purchase for our works at present are built to specifications prepared by ourselves, and it is our aim to cut out every gear or moving part on all machines which is not actually needed for our class of work.

"In specifying for planers, we require only one speed, as our work is so extensive that we can afford to put a planer on one class of work and never change it.

"On vertical milling machines we have specified the design so as to have but one pair of gears between the motor and the cutting tool.

"On large vertical boring mills we have cut out gear boxes and equipped the drive with a big plain pulley and placed a variable speed motor on the ceiling, where the counter-shaft had formerly been put.

"On radial drills we have lowered the speed of the driving shafts and increased their diameter, to reduce the maintenance on bearings."

By a system of tests machines were designed with a view to the economical use of power in operating machines. Mr. Lassiter says :—

"In testing out some of our machines we found that there was a considerable amount of power used for removing a certain amount of stock. A good deal of this power, we found, was absorbed through the friction of unnecessary gears. This is one reason why we have tried to cut out every gear possible on all of the machines which we purchase. It not only saves maintenance, but also cost of power to operate machines."

Keeping machines in service, cutting time between cuts, anticipating repairs and guarding against breakdowns means a great aggregate saving. It means that more work can be done with a certain number of machines when kept in good repair. Of course Canadian shops, or at least few of them, could keep a staff of inspectors busy in an elaborate system but even in the smallest shop a careful investigation and study of each machine will, in a great number of cases, result in an appreciable saving.

TOPICS OF THE MONTH.

It may seem a long step between manufacturing and sentiment but a kind word, an appreciative smile or a commendation for work well done will often increase the efficiency. These are often more effective in eliminating friction than so-called welfare departments planned on an elaborate scale.

* * *

In the January issue of Canadian Machinery we advocated providing sufficient vises in a machine shop. In addition to vises we might add clamps for lathe, planer and shaper, straps, etc. More time is often lost trying to find suitable tools, etc., than in the performance of the machine work. In the interests of economy we would suggest a complete equipment of these devices and a central place for keeping them.

* * *

Well lighted jig, tool and pattern storage rooms, tool room and machine shop are more likely to be kept clean than dark ones.

* * *

Recently a purchasing agent was quoted a price on car journal bearing metal. The metal was satisfactory but the price was high. By having an analysis made, he was able to call for tenders for a metal of the composition shown by tne analysis. The result was that a reliable firm furnished the metal at a considerable reduction over the first price asked. The saving in a year was therefore, considerable. By following this plan for all materials that can be bought by specification, large savings may be made.

* * *

The metal industry is thriving and growing apace in the mother country, in utter disregard of all pessimistic predictions. In this country only an occasional whisper is heard from those who see gloom ahead, and the whole trend of trade is in verification of the loudly expressed confidence of the best informed men in all lines of industry.

* * *

Plans have been prepared for the new machinery hall at the Ottawa Exhibition. Manufacturers of machinery deserve to be well treated by exhibition directors. It is to be hoped that the $75,000 voted a year ago for a new machinery building for the Toronto exhibition, will soon result in the erection of a more modern structure than that now designated as "Machinery Hall."

FOUNDRY PRACTICE AND EQUIPMENT

Practical Articles for Canadian Foundrymen and Pattern Makers, and News of Foundrymen's and Allied Associations. Contributions Invited.

MOLDING HEAVY FLYWHEELS.

By J. H. Eastham.

Firms engaged in casting gas, oil, or steam engine parts, when faced with orders to meet customers' specifications, slightly different from, or "between" standard sizes, are often compelled to alter existing patterns, or to make new ones.

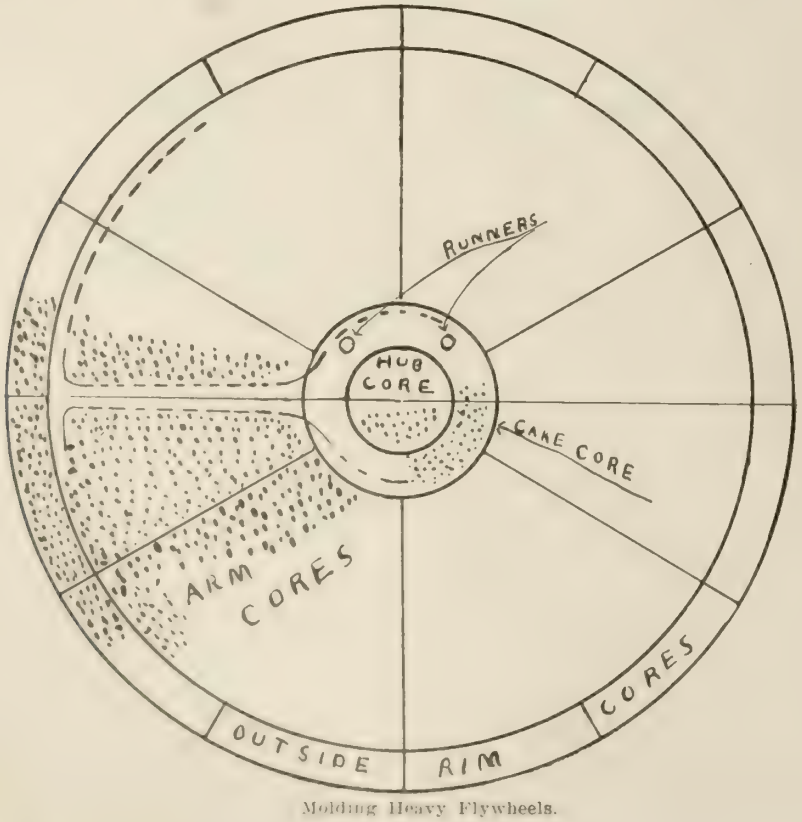
Obviously when an order is placed for a single engine this becomes a costly process, and in the case of flywheels weighing several tons each, can be easily avoided. A common system of moulding these castings is to select a pattern nearest the size required, but a little smaller, and to "lag" up the rim and hub with loose strips, and the arms with sheet lead, an unsatisfactory method at best, adding considerably to cost of production, often resulting in a lumpy casting, and causing much extra machining.

Assuming the job in hand to be of ordinary six-armed type, get a core box made full length from outside of hub to outside of rim, and tapering in width from one-sixth circumference of rim to one-sixth circumference of hub. Each core will thus contain one arm, which may be drawn out endways from hub or thick end.

Cores to form outside of rim are best made in sections about two feet or two feet six inches long, to facilitate handling when placing on stove carriage, and in mold afterwards.

Level a hard bed in floor at full depth of casting, and one foot larger in diameter, and place in centre a round cake core exact size of diamater of hub. Next place arm section cores in position around this; being careful to keep tight up to centre to avoid overlapping, afterwards lowering outside rim cores to place.

If not well equipped with cranes, place as many cores in position as possible during meal hour, to avoid keeping other jobs waiting. Ram up tightly round the whole, (reasonable floor pressure will prevent any strain,) and strike off level with top of cores to form flat joint. Place centre core into position and cover hub with a cake core perforated as desired for runners, insert gate pins, and vent pegs in holes provided in each arm core for purpose.



Stuff joints of all cores with waste, place large square cope part over whole, and ram up lightly. If not in possession of cope sufficiently large, spread one inch or so of sand over cores, and cover with handiest loam plates obtainable. Place runner box in position, large enough to hold at least 15 cwt. of metal in the case of castings weighing three tons or over. This may be dried or green, as considered advisable. Cover runners with ball or flat stoppers, and put weights in position, or bolt the whole down by cross bars to grid or plate in floor if possible.

When pouring, wait till runner box is full before drawing first stopper, and take out remaining 1 or 2, according to size of casting, singly.

Metal for these castings should be melted as hot as possible, and poured as soon as surface "breaks," to obtain best results, and should consist of about 16 per cent. good quality hematite, the remainder, hard scrap.

Good hematite iron, on account of its toughness, minimizes risk of breakage when running at high speeds. Should these castings show signs of sponginess in boring, decrease quantity of hematite a little, and add a small percentage white iron to close grain. Churning is optional, and depends largely on foreman's opinion and quality of metal used.

By the addition or removal of strips from core boxes to alter radii of cores, and thickness or depth of rim, and keeping in stock of pattern shop several sizes of arms, one set of boxes will serve for several sizes of castings.

Molding Heavy Flywheels.

PATTERNMAKER'S TOOL CHEST.

By H. J. McCaslin.

The accompanying photographs show the manner in which the up-to-date and progressive patternmaker carries his tools, and which has to a great degree replaced the strong box of bygone days.

This handsome case and contents of selected tools forms one of the finest pattern-making equipment that ever came under the writer's notice.

The case was designed and made by J. E. Rexroth, an employe of the Wellman, Seaver, Morgan Co., of Cleveland, O., through whose courtesy the photograph was obtained.

The body construction is that of a substantial sample case which it closely resembles as shown in Fig. 1. While it might be said one would not inspire to carry it any further than necessary, very little trouble would be experienced in getting it to and from the car, thus saving the expense of the expressman, to say nothing of the delay and vexation in not always being able to get your tools at the expected time.

Its proportions permit a 26-inch saw by removing the handle of the saw to be carried, and also a 24x14 inch. steel square. The heavier tools, as the plains, are carried at the bottom of the case

Fig. 1– Patternmaker's Tool Chest—Closed.

below the lawer drawer, which is shown removed, Fig. 2.

Attached to the back of the panel which is dropped down so as to expose the chisels and bits and their manner of arrangement and support is the steel square, shrink rules and triangles. To the young patternmaker who contem-

Fig. 2—Patternmaker's Tool Chest—Open.

plates leaving the home shop at the completion of his term of instruction and taking to the road in search of experience and wealth, secure a case similar to that here described, if you have not already done so. Should you not care to enlist as heavily into the undertaking as herewith shown, invest in a good substantial suit case and fit it up with drawers which will answer the purpose admirably.

CANADIAN AGENCY HILL & GRIFFITH.

The Rupert G. Bruce Co., Toronto, have been appointed Canadian agents for Hill & Griffith, Cincinnati. The lines of this firm which will be carried in stock in Toronto, include stove plate facing, heavy machine bag facing, "Ideal" core wash, Haskin patent ventilated chaplets, "Faultless" core compound, Rhode Island heavy bag facing, H. & G. blacking, white pine charcoal facing, special taper snap flask of sheet steel with malleable trimmings, tumbling barrels, cupolas, electric and hand cranes, brass melting furnaces, both oil and coke fired, cupolo blocks and bricks, fire clay and molding sands.

Hill & Griffith have seacoal mills in Birmingham, Alabama, and plumbago mills in Cincinnati.

Mr. Hill, who is known to the trade as "Honest John," has some strong arguments in favor of his products and calls attention to the H. & G. facings by means of an old and trite saying: "If you want to find out if a horseshoe is hot, pick it up. You are not obliged to take the blacksmith's word for it."

"Likewise," says John, "you are not obliged to heed our argument which necessarily has to do with our foundry facings and blackings, their use and abuse."

PITTSBURG EXHIBITION.

Final arrangements for the exhibition of foundry and pattern shop equipment, machine tools and supplies, to be held under the auspices of the Foundry and Machine Exhibition Co., successor to the Foundry and Manufacturers' Supply Association, at Pittsburg, during the week of May 22, 1911, were made at a meeting of the executive committee of this organization held at the Fort Pitt hotel, Pittsburg, Jan. 20 and 21. The buildings of the Western Pennsylvania Exposition Society, on Duquesne Way, in the centre of the Pittsburg business district, have been obtained for this exhibition of foundry and pattern shop equipment. A total of approximately 35,000 square feet of floor space will be available in two large buildings and in a temporary structure which will be erected between these buildings. All of the operating exhibits, such as heating and melting furnaces, core ovens, mold and ladle dryers, etc., will be located in the temporary building. The facilities provided for exhibition purposes are unexcelled, and shipments can be unloaded onto the grounds from Pennsylvania railroad sidings. It has been decided to conduct the exhibit during at least two or three evenings of the week, which will afford an opportunity to many of the foundry operatives of the Pittsburg district to attend the show.

The cost of space has been fixed at a minimum of only 50 cents per square foot, with an additional cost of $10 for corners. An exhibition permit, for which a charge of $25 will be made, will also be required by all exhibitors, as well as those conducting business of any kind in the exposition buildings. The large music hall on these grounds has been obtained for one evening during the week for a high-class entertainment to be given by the Foundry and Machine Exhibition Co. The headquarters for the exhibitors will be at the Fort Pitt hotel.

During this week the annual conventions of the American Foundrymen's Association, American Brass Founders' Association and the Associated Foundry Foremen will be held in Pittsburg, and the attendance of foundrymen from all over the United States and Canada promises to be unusually large. As this city is the centre of the steel manufacturing industry of the United States, and as some of the foundries in this district are among the largest and most modern in the country, unusual opportunities will be afforded foundrymen to familiarize themselves with the practice of these works and an extensive plant visitation program is now being outlined.

BREAKING OF GATE IN MOLD.

Experienced molders always know what the breaking of the gate in a mold before dumping means. It always indicates, in brass or bronze, that the metal is not good and that it contains impurities which render it red-short. By the breaking of the gate in the mold is meant that it breaks or cracks itself while cooling. In good metal, it remains firm so that when the mold is dumped, the castings, gate and runner are solid.

There are several elements that will cause red-shortness in brass or bronze, but sulphur is the principal one. As it causes red-shortness in iron or steel, so it produces the same result in the copper alloys.

Sulphur is very readily introduced into bronze or brass by the fuel, and especially when coke or coal, instead of charcoal, is used as the covering for the metal in the crucible. These fuels always contain more or less sulphur which is introduced into the metal to a greater or less extent. Charcoal, however, contains no sulphur and this is why it is so good a covering for molten metals.

If molders are experiencing difficulty from bad castings and the reason is not clear, let it be noticed whether the gate cracks in the mold, and if so look for the presence of sulphur in the metal. It has been found to be the cause of some of the difficulties encountered in the brass foundry.—Brass World.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

FOUNDRY AND MACHINE SHOP.

MONTREAL. The Montreal Harbor Commission has purchased a block of property near the river, on Notre Dame Street. Repair shops will be erected.

OXFORD, N.S.—The Oxford Foundry & Machine Co. have the contract for the heating equipment for the Bank of Nova Scotia's new building here.

WELLAND, ONT.—The Robertson Machinery Co. has made an assignment to J. F. Gross, for the general benefit of its creditors. The company has been insolvent for some time.

GALT—The Galt Foundry Co. have their new plant completed and expect to take off the first heat in a few days. Wm. E. Demill, formerly of Clark & Demill, Hespeler, is manager of the new company. A. J. Colvin is associated with him.

WINDSOR, ONT.—Plans are being drawn for a new dry-dock at Amherstburg, with a 600-foot capacity. It is also intended to have a shipbuilding plant, with the necessary machine shops. Windsor, Amherstburg and Toronto capitalists are interested in the scheme, which will cost about $250,000.

CALGARY, ALTA.—Mayor Mitchell advocates the erection of a municipal repair shop. He is of the opinion that much time and money is lost through sending small jobs to outside machine shops for repairs, instead of having a couple of men and proper machinery to handle them.

WEST TORONTO—The C. P. R. has secured a permit for the erection of a $20,000 repair shop here, on the west side of Keele Street, north of the subway.

LETHBRIDGE, ALTA.—Donovan & McCrea are erecting a building at Bow Island to be used for a machinery business.

HESPELER, ONT.—W. Ewald, of Preston, has been appointed manager of the Hespeler Machinery Co.'s shop.

GOWGANDA, ONT.—The machine shop at the Bartlett mines here was destroyed by fire recently.

MONTREAL—The Canadian Rotary Machine Co. will locate here.

THE WATEROUS ENGINE WORKS have submitted building specifications for an addition to their present factory, to cost $45,000.

MAISONNEUVE, QUE.—Street construction work has just been commenced on the new $100,000 building being erected for the United States Shoe Machinery Co. The masonry and carpentering contracts are the only ones let, in addition to the foundation and steel construction.

VANCOUVER, B.C.—The Western Steel Corporation have purchased 300 acres on the south side of the Fraser river. About $2,000,000 will be expended on construction of buildings and wharves and instalation of machinery.

MONTREAL—The National Steel Co. are erecting a large plant at Longue Pointe, to cost one million dollars. General contract awarded to Peter Lyall & Sons.

MORRISBURG, ONT.—The Tack Factory has now thirty machines in operation, and twenty more have just arrived. There is also in operation one shoe nail machine with a capacity of one-half ton a day. Mr. Russell has just returned from Toronto, where he secured orders amounting to over nine tons. Two more expert tack makers have arrived, and are now at work.

HALIFAX, N.S.—Fred M. Brown, formerly of the Steel Co., whose appointment as vice-president and general manager of the Nova Scotia car works was announced recently, is here. Mr. Brown is a Montreal boy and has a thorough grasp of mechanical affairs, as well as a mastery of the details necessary to the discharge of the duties as purchasing agent in a great company like the Dominion Steel Corporation.

MONTREAL—New plans of the C. P. R., as announced by W. Whyte, here, include 100 miles of double-tracking and 300 miles of new track in the west. New yards will be laid out at Regina, Moose Jaw and Medicine Hat. Four new steel bridges will be erected. Old 60 pound rails on the Manitoba and Northwestern branch will be replaced by 80 pound steel for a distance of about 160 miles.

OWEN SOUND, ONT.—A Cleveland firm is contemplating the erection of a cold-pressed steel works here.

BROCKVILLE, ONT.—Wm. J. Nute & Sons have purchased the boiler works owned by Black Bros. The new firm will manufacture boilers, hot water heaters and do general repair work.

VANCOUVER, B.C.—W. Price, of Seattle, general manager of the Western Steel Corporation, proposes to start the construction of a $500,000 merchant steel plant near Sudbury by April 1. The directors have secured 300 acres.

WELLAND, ONT.—The Canadian Automatic Transportation Co., with head office in Toronto, will erect a plant here for the manufacture of automatic carriers. The principal product is a storage battery truck scale for handling freight.

COBOURG, ONT.—A new mill has been erected for the Provincial Steel Co. here, and machinery is being installed.

MONTREAL—Foss & Fuller, machinery dealers, have dissolved.

TORONTO, ONT.—Application has been made to the Provincial Secretary of Ontario on behalf of the Timmins-McMartin-Dunlop Syndicate for a charter for a milling, concentrating and refining company of $500,000 capital stock. The name of the company is to be the Porcupine Gold Mining Co. It is proposed to erect at once a mill having 30 stamps at the outset, and so built as to enable its capacity to be easily increased upon demand. Besides working on the ore of the mining interests associated in the company, the plant will be used on custom business.

HALIFAX, N.S.—The city council has voted to give exemption from taxation for 20 years to the Nova Scotia Car Works, which is to take over the works of the Silliker Car Co. Also the new company is to receive free from the city 5,000,000 gol. of water every year.

CALGARY, ALTA.—The Board of Trade is in communication with American inquirers who are considering the establishment here of works for the manufacture of gas engines, stoves and heating apparatus.

GALT, ONT.—The Galt Foundry Co., whose new premises were completed this month are already making castings for the trade.

TORONTO—The Fairbanks-Morse Co. have taken out permits for a new $13,000 foundry and foundry cleaning and pattern room, at 1363-1369 Bloor Street West.

WEYBURN, SASK.—The Birrell Motor Plow Co., of Winnipeg, are negotiating with the authorities regarding the establishment of a factory here.

TORONTO, ONT.—J. L. Richardson & Co., dealers in machinists' and foundry supplies, have assigned to Richard Tew.

REGINA, SASK.—The Holt Caterpillar Co., of Stockton, California, will establish a distributing centre here in the spring for their traction engines.

LONDON, ONT. An automobile factory is to be located here. Hugh Kennedy, of Galt, and W. J. and Frank Reid, of this city, are interested.

GANANOQUE, ONT.—The D. F. Jones Co. has added a night gang and is keeping its rolling mills in constant operation.

AMHERST, N.S.- Extensive improvements are being made in the shops of the Canada Car Co. here. There are orders on hand to keep the works busy till next June.

ST. STEPHEN, N.B.—The Maritime Edge Tool Co., here, has made large additions to its factory.

ORILLIA, ONT.—The Canadian Refining & Smelting Co. has its building up, and is putting in the plant for treating high-grade Cobalt ore.

SHERBROOKE, QUE. The Canadian Fairbanks Co., manufacturers of weigh scales, will double the manufacturing capacity of their plant here.

QUEBEC, P.Q. The Dorchester Electric Co. is to build machine shops here, at a cost of $200,000.

CHATHAM, ONT.—The Dowsley Spring & Axle Co. is making extensions to its plant.

OTTAWA, ONT.—Henderson Bros., of Bruton, England, have decided to establish a factory in Ottawa for the manufacture and hair-cloth machines and patent horizontal saws.

LONDON, ONT.—The Superior Machinery Co. has obtained a charter.

TORONTO, ONT.—Sellew Motors, Ltd., has obtained a charter.

VICTORIA, B.C.—Among the companies either licensed or registered during the last week of December to do business in British Columbia, are the Burrill Rock Drill Co., Record Foundry & Machine Co., Hallidie Machinery Co.

JOLIETTE, QUE.—The Joliette Steel & Iron Foundry is the name of a new manufacturing concern at Joliette, Que. The company intend dealing in machinery and supplies, steel and iron castings of all kinds. They have opened an office and show room in Montreal, under the management of J. D. Query. The new company has absorbed the business formerly carried on by the Joliette Foundry Co. They also contemplate manufacturing some specialties in the near future.

HAMILTON—Fire, supposed to have been caused by the ignition of crude oil used to facilitate the handling of rolled steel, completely destroyed the Hamilton Steel & Iron Company's rolling mills, at the corner of Queen and Barton, recently. The frame shell, in which the valuable rolls, furnaces and hot beds were located, was burned to the ground. The forge and axle department, which is situated immediately west of the mills, was also badly damaged. The loss is estimated at $12,000.

LONDON—Alexander Gauld, brass finisher at the Labatt Box Co., is organizing a foundry company here, which promise to employ in a short time 100 men. The output of the foundry will consist of all sorts of plumbers' castings, pipings, etc.

ST. CATHARINES, ONT.—The Steel & Radiation Co., of Toronto, has agreed to erect a new factory here, to begin active operations by the end of the year, employing 100 men with an annual wage roll of $50,000 for the first three years, and afterwards 250 men with an annual wage roll of $125,000. The city gives the company a site of 35 acres, with a fixed assessment of $5,000 for three years and $10,000 for the next seven years.

ELECTRICAL NOTES.

TORONTO—Debentures to the amount of one million dollars will shortly be issued by the city in connection with the construction of the civic power plant.

VICTORIA, B.C.—The electric lighting by-law ($25,000) was carried.

CALGARY, ALTA.—The machinery at the big dam of the Calgary Power Co., on the Bow river at Kananaskis, is nearly all installed, and if nothing unforeseen occurs the company will be in a position to supply power in Calgary by the date agreed upon, April 1, 1911.

SASKATOON—E. L. White, city electrician, has prepared estimates calling for an expenditure of $140,656 for a light and power plant. The proposed changes would double the capacity of the works.

WINDSOR, ONT.—Windsor has secured the Canadian branch of the Moloney Electric Co., of St. Louis, Mo. The Moloney Company manufacture electrical machinery on an extensive scale. They are erecting a temporary building, in which manufacturing will probably start within two months.

ELKO, B.C.—The British Columbia Electric Co. will uild a plant here for developing power.

GRAND FALLS, N.B.—The Maine & N. B. Electrical Power Co., of St. John, N.B., will build a new line here and erect a large power plant.

HESPELER, ONT.—A municipal electric lighting system will be installed here.

OTTAWA, ONT.—The Ottawa Electric Railway is building a new power house.

WATERLOO, ONT.—$50,000 will be spent on an electric lighting plant here.

OTTAWA, ONT.—American and English capitalists will establish an electric smelting plant at Chat's Falls, on the Ottawa river, in the spring.

PORCUPINE CITY, ONT.—C. L. Sherrill, of Buffalo, is preparing to erect a power plant here to facilitate the development of this district.

CAMROSE, ALTA.—The municipality-owned power plant here has been opened and is now in operation.

STRATHCONA, ALTA.—Steps are being taken to increase the capacity of the municipal electrical plant. About $70,000 worth of machinery will be purchased, including a 600 kilowatt generator and engine and the necessary boilers.

KINGSTON, ONT.—Mr. Beach, of Iroquois, has options on water powers adjacent to Calabogie, Renfrew Co., Que. He is planning two generating plants, a main one at High Falls, and a secondary one at Brockville.

WELLAND, ONT.—The Falls Power Co. has sold its lighting system to the Welland Electrical Co. This includes the street lighting here.

PORT HOPE, ONT.—A by-law granting a 30-year franchise to the Seymour Electric Power Co. has been carried.

WINNIPEG—The Winnipeg Electric Railway has secured a permit for a new turbine power building, the estimated cost being $72,000. It will have a turbine engine of 12,000 horse-power.

INGERSOLL, ONT.—The by-law to appoint a commission to control the electric light and power utility was carried.

GRAND FALLS—The Grand Falls Power Co., of which Sir William C. Van Horne is one of the leading spirits, is preparing to begin active operations towards the development of a big industry at the Falls.

WINNIPEG, MAN.—The Board of Control accepted the tender of the Seamens Dynamo Works, Toronto, for the 500-kilowatt generator sets for the power station. Their tender amounted to $16,410.

BROCKVILLE, ONT.—J. Wesley Allison, of the New York & Ontario Co., states that drills, boring machines, boilers and hoisting apparatus for the power plant at Waddington, were now being secured, so that work could be commenced early in the spring, and that electrical machinery, water wheels and other machinery necessary had been contracted for.

BRANTFORD, ONT.—Hal Donly, Simcoe; W. S. Brewster, R. E. Ryerson, John Muir and W. D. Schultz, of Brantford, are applicants for a charter for an electrical radial line from Brantford to Port Dover.

BOWMANVILLE, ONT.—The plebiscite in favor of the electric light being managed by commissioners carried.

BROCKVILLE, ONT.—The by-law to amalgamate the light and water commissioners carried.

MEDICINE HAT, ALTA.—The new electric power house here has been completed and machinery is being installed. A regulator station is being erected near the power house.

WEYBURN, SASK.—Owing to delay in the arrival of machinery, the new power house and electric service will not be ready for use until March.

ST. JOHN, N.B.—The Maine & New Brunswick Electrical Power Co. will build a line from its plant at Aroostook Falls to Limestone, Van Buren and St. Leonards, running near Grand Falls. Besides selling power to the towns, it is the object of the company to furnish energy for the construction of the large paper mill to be built on the St. John river at Grand Falls.

WINNIPEG, MAN.—It is reported that private corporations, believed to be backed up by C. N. R. interests, are securing every available hydro-electric site on the Winnipeg river below Lac du Bonnett and Point du Bois, where the city is completing its $2,000,000 power plant. There is a rumor to the effect that it is planned to underbid the city in the sale of surplus power.

HAMILTON, ONT. The Hamilton & Port Dover Electric Railway Co., which has obtained provincial charter to construct an electric line between Hamilton and Port Dover, at an estimated cost of $1,000,000, will build its power house at Caledonia. George Lynch Staunton, K.C., Hamilton, is to be president of the company.

OTTAWA, ONT.—Sparks Street, in this city, is to have a "White Way." The municipal electric department has charge of installing the service and expects to have the lights going before the end of January.

QUEBEC, P.Q.—The Dorchester Electric Co. has obtained the consent of the municipal authorities to extend its system into this city and sell electricity.

HAMILTON, ONT.—The directors of the Dominion Power & Transmission Co. have placed an order with the Canadian Westinghouse Co. for a new generator, to be installed at the former company's power works at De Cern Falls. The capacity of the generator is to be 8,500 h.p., and its cost to be $200,000. The power company is also arranging to build another sub-station in Hamilton. This will cost $100,000.

BOWMANVILLE, ONT.—A franchise was voted to the Seymour Power & Electric Co. in this town, on Dec. 27.

PETERBORO, ONT.—The Can. Gen. Elec. Co. will construct a power house on the waterworks dam, near here. Bids are now being received.

NEW COMPANIES.

TORONTO, ONT.—The Augustine Automatic Rotary Engine Co., capitalized at $1,000,000 has been incorporated.

LONDON, ONT.—The "Superior Machinery Co." has been incorporated. The promoters are J. Fitzgerald, E. W. Scott, G. E. Scott, and T. Bryan, manufacturers, and J. B. P. Tanton, merchant, all of this place. They have taken over the business formerly known as The Superior Repairing and Mfg. Co. and will deal in all kinds of machinery. The head office will be here.

TORONTO, ONT.—Barr Registers Co., has been incorporated with capital of $50,000. They will manufacture registers and store devices. Among the directors are W. H. Matthews, A. E. Bywater and J. A. Stevenson, M.D., of Trenton.

ST. JOHN, N.B.—C. J. Salmon, W. G. Salmon, H. G. Adams, M. A. Hatheway and G. Dodge, of St. John, are applying for incorporation as "The Globe Steam Laundry, Ltd.," to be located here.

OTTAWA, ONT.—The North Fork Power Co. have been incorporated.

The Byrnes Mfg. Co., of Collingwood, has been incorporated. They will carry on a wood-working business.

VANCOUVER, B.C.—The North American Lumber Co. has been incorporated in British Columbia. The manager, H. L. Jenkins, has his head office here in the B. C. Trust Block, on Pender Street.

HAMILTON — Hamilton Machinery Co., Hamilton, Ont., have been incorporated to carry on business of mechanical engineers and manufacturers of machinery, with a capital stock of forty thousand dollars. Those

ESTABLISH A MODERN TAX-FREE ALCOHOL DISTILLERY
We have a Good Proposition for Motor Mfrs.

Having exported our Stills in large amounts for many years, and already having several live Eastern agencies we are now open to establish additional agencies and invite correspondence to that end, looking after our old customers and prospective buyers by special successful demonstrative methods for making Alcohol, Apple Jack, Aguardiente, Mescal, Tequila, Peach Brandy, Whiskey, etc. Most modern and simple. All sizes, 5 to 500 gallons daily capacity distilling apparatus.

ARE YOU LOOKING FOR information relating to INDUSTRIAL or DENATURED ALCOHOL DISTILLING APPARATUS and the amazing possibilities of the utilization of waste farm products and wood waste by superheated steam distillation, the distilling apparatus as used by us; the principle involved, also the methods of chemical control and disposal of the product and by-products? We will gladly say to you:

Denatured Alcohol to-day is of the greatest untold benefit to the American motor people. It opens an absolutely new field for investment for progressive paper pulp and chemical fibre mills, paint, varnish, soap and candle makers, gardeners, farms and garbage plants, saw-mills, lumbermen and canneries. The Automobiles and the Navies of the world clamor for this new tax-free cheaper industrial alcohol. May we expect some encouragement from the more patrotic pioneers for this new American Industry? The field is new and profitable, and you can practically have the business your own way by starting now. We are makers of an apparatus for the production of this denatured or industrial alcohol; we build and install plants—large or small. The initial cost of a plant is small; the financial risk—if any—is trifling. The equipment is such that it can be added to at any time without disturbing the original installation. Address

THE WOOD WASTE DISTILLERIES CO., Inc.
WHEELING, W. VA., U.S.A.

incorporated are M. W. Best, salesman, F. W. Woods, manufacturer, G. F. Webb, contractor, all of Hamilton, Ont., and N. B. Mancill, salesman, Vancouver, B.C., and R. F. Mancill, salesman, of Goderich, Ont.

MONTREAL—Standard Machines Co., of Montreal, has been incorporated to manufacture all kinds of engines and machines. G. V. Cousins and O. B. MacCallum, barristers, P. F. Brown, stenographer, W. R. Ford, clerk, S. T. Mains, bookkeeper, all of Montreal.

MONTREAL—Canadian Steel Foundries, head office at Montreal, have been incorporated to manufacture and deal in machinery. G. O.Cousins and O. B. MacCallum, barristers, S. T. Mains, accountant, P. F. Brown, secretary, and W. R. Ford, clerk, all of Montreal, are the incorporators.

VICTORIAVILLE, QUE.—The Victoriaville Chair Mfg. Co. has obtained a charter.

ST. JOHN, N.B.—Michael Sullivan, of Kingston, has been awarded the contract to build the armory here. It is estimated the building when completed will cost about $250,000.

SHERBROOKE, QUE.—Simoneau and Dion have been awarded the $200,000 contract for an office building for the Quebec Railway, Heat and Power Co., at Quebec. The building must be completed by November.

VANCOUVER, B.C.—The Investors' Guarantee Corporation will erect a fifteen-storey block here at an estimated cost of $500,000.

Vancouver, B.C.—The Hudson's Bay Co. propose to erect a six or eight storey steel building here.

SUDBURY, ONT.—The Casey-Shaw Lumber Co. has obtained a charter.

MONTREAL, QUE.—Canadian Rotary Machine Company, capital stock $600,000. To control Wilhelm von Pittler's system of rotary engines and machines in Canada.

MONTREAL—National Bridge Co., Montreal, Que; capital stock, $1,000,000. To carry on a general bridge building business and to erect the necessary plant.

MUNICIPAL.

PENTICTON, B.C.—By-laws in favor of the installation of a waterworks and electric lighting system were carried recently.

ESQUIMALT, B.C.—The position of general manager of the Esquimalt Waterworks Co. rendered vacant by the death of T. Lubbe will not be filled, the directors undertaking the management of the business.

TORONTO, Ont.—R. Chadwick, the city's bridge engineer, has resigned to accept a position with a New York contracting firm. The Board of Control has appointed Mr. Cousins his successor.

WESTVILLE, N.S.—The new pump has arrived from Toronto. Mr. McIntyre of the Canada Foundry Co. will superintend the erection.

SHERBROOKE, QUE.—The City Council has awarded the contract for power development to Morrow and Beathe, of Peterboro', their tender of $51,220 being the lowest. This amount covers the construction of the dam and power house.

STRATHROY, ONT.—The by-law to raise $6,000 for improvements to the electric light and waterworks systems carried.

ORILLIA, ONT.—The by-law granting the Canada Refining & Smelting Co. certain privileges was carried.

GODERICH, ONT.—The by-law to raise $26,000 by debentures for the building of a storm sewer and referendum towards building new municipal buildings were both carried.

EDMONTON, ALTA.—The City Council provisionally passed debenture by-laws to raise and expend $456,000 on public works. These include $167,000 for a bridge over the Saskatchewan River.

STRATHCONA, ALTA.—Tenders addressed to David Ewing, chief engineer power house, here, for Engine, Boilers and Generators will be received up to March 1st, 1911. Specifications may be had from the city engineer, A. J. McLean.

OTTAWA.—It is announced here that a new steel bridge will be built over the Ottawa river at Temiskaming. The Federal Government will contribute $50,000, Quebec $15,000 and Ontario an amount to be fixed later.

NORTH VANCOUVER, B.C.—The Second Narrows' bridge connecting up the north and south shores of Burrard Inlet with a proposed $1,250,000 traffic and railway bridge is now assured since the electors have voted the necessary funds.

PORTAGE LA PRAIRIE—The city council has appointed a special committee to ascertain the possibility of purchasing a central electric light and gas plant with the view of a municipal owned plant to furnish the city with light and power.

VICTORIA, B.C.—On the recommendation of the water commissioner, the city will pur-

chase 473 Trident water meters of various sizes at a cost of $7,500; 15,000 feet of 12 in., 10,000 feet of 8 in., 35,000 feet of 6 in., 80,000 feet of 4 in. Mannessman's steel tubes at a cost of $80,000; and 460 gate valves of various sizes at an estimated cost of $4,000; and 15 tons of pig lead. These supplies will be used in extensions of the distribution system.

HARRISTON, ONT.—A complete new waterworks system is being installed here.

ST. CATHARINES, ONT.—$180,000 will be spent on the waterworks plant here.

NORTH VANCOUVER, B.C.—The municipality is in the market for $50,000 worth of cast-iron pipe.

PEMBROKE, ONT.—The municipality is in the market for 6,000 feet of 18-inch lapwelded or riveted steel piping.

NELSON, B.C.—The city will install manual training equipment in the schools here. Machine-tool equipment will be required.

RIDGETOWN, ONT.—The plebiscite for waterworks carried.

OWEN SOUND, ONT.—The by-law to rebuild two bridges was carried.

MITCHELL, ONT.—A by-law to run the municipal electric light and waterworks by a commission carried.

HARRISTON, ONT.—The by-law for municipal waterworks carried.

WESTON, ONT.—The by-law for a commission to manage the electric lights and waterworks was carried.

VICTORIA, B.C.—The $150,000 waterworks loan by-law and Sooke Lake by-law both carried.

TORONTO.—The city will apply for legislation to issue debentures to raise $626,544 for a new waterworks intake pipe, a six-foot steel conduit, and the necessary additional pumping mains.

SAULT AU RECOLLET, QUE.—A modern waterworks system will likely be installed here in the near future.

VANCOUVER, B.C.—The ratepayers have authorized the issue of $400,000 of debentures for waterworks extension.

WINNIPEG, MAN.—Tenders will be received up to 11 a.m., on Monday, February 6th, 1911, for the manufacture, delivery and erection complete of two pumping plants each of a capacity of one million imperial gallons per 24 hours. Specifications, forms of tenders may be obtained at the office of the City Engineer, 223 James Avenue, Winnipeg.

BROCKVILLE, ONT.—The municipally owned waterworks system here shows a net surplus for the past year of $2,406.92.

BOWMANVILLE, ONT.—The indebtedness of $19,280 incurred by the late Durham Rubber Co. with this municipality and taken over by the Goodyear Tire Co., of Canada, has been wiped out by the carrying of a by-law granting a bonus of an equal amount. A partial exemption from taxation and a fixed assessment have also been granted the Goodyear Company.

CALGARY, ALTA.—Commissioner Graves estimates that between 25 and 30 miles of water mains will be laid during the present year. The waterworks for 1910 shows a surplus of $3,335.36.

BOWMANVILLE, ONT.—This municipality is considering the installation of waterworks. The proposed source of water supply is from springs seven miles distant. John Lyle, clerk.

Saw Mill and Planing Mill News.

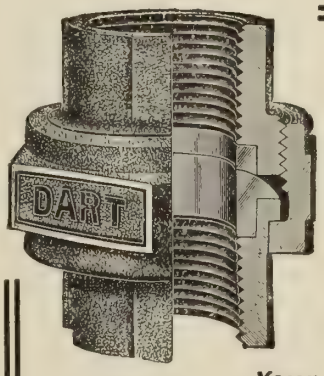
THOROLD, ONT.—The Colonial Wood Products Co. has just erected an addition, 72 by 45 feet, to its mill to provide for additional wet machine capacity, enabling it to increase the output of mechanically ground wood pulp. This company commenced operating in February and the extension referred to has been necessitated by the demand for its ground wood. The plant is operated electrically, having two grinders at present and four wet machines.

CHARLOTTETOWN, P.E.I.—The woodworking steam mills of Barnard Creamer, of Souris, have been totally destroyed by fire. Loss, $8,000. No insurance. Another mill, that of M. F. Schurman and Co., Summerside, was also burned.

LETHBRIDGE, ALTA.—Becker and Yates, with headquarters here, will open a lumber yard, and do a general lumber business.

FORT FRANCES, ONT.—Work has commenced on the new mills of the Shevlin-Clarke Co., here. The erection will be complete by June 1st.

RICHMOND, QUE.—Messier & Desmarais have purchased the Haslett portable saw mill plant at Tronholmville and will remove it to Richmond and make additions to the plant.



STEWART, B.C.—The Portland Canal Mining Co. are building a new saw mill here.

KINSELLA.—W. H. Kennedy is starting a lumber yard here.

Ker & Goodwin

Brantford, Canada

CHILLIWACK, B.C.—The Abbotsford Timber and Trading Co. are opening a lumber yard here.

GOLDEN CITY, B.C.—The new mill of the Columbia River Lumber Co., here, has been enclosed and the placing of machinery is being proceeded with. A Fairbanks engine will furnish the power.

FORT GEORGE, B.C.—Three more saw mills will be established in this district and be in readiness for operations in the spring. Two of these will be located on the Nechaco river and the third on the Fraser river, six miles above Fort George.

VANCOUVER, B.C.—The lumber mill and limits of the Salmon River Lumber Co. in Langley municipality have been sold to the Western Lumber and Shingle Co., with head office in Vancouver, for $60,000. The purchasers have placed Mr. Mitchell in charge. It is their intention to operate the mill and possibly install a shingle mill and dry kiln.

RIDGETOWN, ONT.—The Mills of the Howard Cooperage and Lumber Co. will be re-opened, having been closed for two years. Lumber, baskets, veneer and fish boxes will be handled.

DAUPHIN, MAN.—T. A. Burrows of this place will build a large saw mill on the McLeod River, 26 miles west of Wolf Creek. Building operations will be commenced this winter.

CHATHAM, N.B.—J. B. Snowball Co. are altering and extending their large saw mill here. It has been lengthened 32 feet, and a filing room added. Two of the three gang saws will be replaced by an eight-inch band mill, a seven-inch re-saw band, and a twin rotary slabber.

New Westminster, B.C.—Galbraith & Sons intend erecting a saw mill and factory on Lulu Island. The saw mill is to be 40 by 225 by 60 feet. The plant is to be up-to-date, having a large dry lumber shed 45 by 65 feet, dry house 30 by 120 feet, and a loading plant 30 by 40 feet. The mill will be a three-storey one.

CARIBOU, N.B.—S. W. Collins & Son's lumber mill here back of the Vaughn House, was wholly destroyed by fire recently. The loss was $7,000, insurance $1,000. This mill may not be rebuilt, as a mill in that spot is said to be not a very profitable proposition.

OWEN SOUND, ONT.—The Galbraith-Bumstead syndicate are rushing the work on their new planing mill, sash and door factory here. Approved mill construction is being used.

LETHBRIDGE, ALTA.—The Farmers Lumber Co. are building a lumber yard here.

General Manufacturing

MOOSE JAW, SASK.—The Western Manufacturing Co., Regina, has purchased the Saskatchewan Sash and Door Co., here, and will make additions to the plant.

ORILLIA, ONT.—The Canada Keg & Barrel Co. will commence the erection of factory buildings here in the early spring. A site of 5 acres has been granted by the town.

BERLIN, ONT.—The L. McBrine Co., trunk manufacturers, and the Art Glass Co., are each planning to construct large additions to their present factories. In addition, the Felt Boot and Rubber Manufacturers will build a box factory for their own use.

REGINA, SASK.—The Massey-Harris Co. are building a track warehouse here, 96x48 feet and two storeys high. They will also build track warehouses at Swift Current and Arcola.

REGINA, SASK.—The Sawyer-Massey Co., of Hamilton, will erect a warehouse and distributing agency here. The construction will be of brick and steel throughout with concrete floors. The building is to be steam-heated.

SARNIA, ONT.—H. Diver has purchased a site from the Cleveland-Sarnia Saw Mills Co., and will commence the establishment of a new industry here. The new firm will manufacture doors, especially of the better class, veneered and fancy hardwood. The main building will be 80x200 feet, two storeys in height, and of reinforced concrete. There will be a storage building of 20x200 feet, dry kilns of 60x60 feet, and a building for the steam power plant of 40x80 feet. Work on the erection of the new structure will be commenced forthwith.

RIDGETOWN, ONT.—T. G. Johnston has taken an interest in the Leitch basket works. A new veneer machine, rip saw, new boiler and engine will be placed in the factory.

LONDON, ONT.—A large knitting concern from the United States has leased a building here and will commence operations in the near future.

OTTAWA, ONT.—The Beaver Board Co., of Buffalo, N.Y., has purchased land in Ottawa upon which to erect a factory for the making

MONTREAL, QUE.—The pulp and paper mills to be established by Price Bros. & Co., on the Riviere au Sable, and for the building of which $5,000,000 has recently been raised by the sale of the company's bonds in London, are to be ready for operation by June, 1912. The new industries are expected to bring into existence at that point a town of 4,000 or 5,000 inhabitants. A water power development that can be depended on to maintain 14,000 h.p. will be begun as soon as possible.

AMHERST, N.S.—The Amherst Boot & Shoe Co., whose plant turns out 1,000 pairs a day, is doubling its manufacturing capacity.

Building Notes.

VANCOUVER, B.C.—Extensive alterations will be commenced in the spring on the abattoir and packing plant of P. Burns & Co. About $200,000 will be expended.

VANCOUVER, B.C.—Mr. Lester will erect a $100,000 six-storey building here in the spring. Up-to-date equipment will be a feature of the building throughout.

PRINCE RUPERT, B.C.—The Pacific Construction Co., of Victoria, B.C., has been awarded the contract for the marine department depot here. The contract price is $150,000.

HAMILTON, ONT. — The International Harvester Co. have let a contract for a new office at their plant to G. E. Mills. Cost, $40,000.

CALGARY, ALTA.—The C.P.R. will erect a big hotel here.

ST. CATHARINES, ONT.—The city has decided to give 35 acres of free land to the Steel and Radiation, Limited. The company will spend $50,000 on buildings.

REGINA, SASK.—Hand Bros. & Nellermoe Co., of Winnipeg, will erect a $50,000 implement warehouse here. The headquarters of the firm will be moved here.

REGINA, SASK.—The Toronto Type Foundry Co., of Toronto, are preparing plans for a $20,000 warehouse. It will have steam heating, plumbing and an electric hoist.

TORONT, ONT.—The C.P.R. will erect at the corner of King and Yonge streets, a sixteen storey building, costing over $1,000,000. It will be of steel, faced with glazed terra cotta and will be one of the finest office buildings in the world.

SASKATOON, ALTA.—The Canadian Fairbanks Co. will erect a block here on Twenty-Third Street.

SASKATOON, ALTA.—The International Harvester Co. have a scheme in view which will extend their premises considerably. It is also stated that the J. I. Case Co. will build in this city.

SASKATOON, ALTA.—The American-Abell Engine and Thresher Co. also intend locating here. They have erected offices and a warehouse opposite the C.P.R. depot.

SASKATOON, ALTA.—The Hart-Parr Co., of Charles City, Iowa, manufacturers of oil and gasoline traction plow engines have located offices here as headquarters for Northern Saskatchewan and Northern Manitoba.

MONTREAL, QUE.—The Engineers' Club will make extensive improvements to their clubhouse here. The plans call for an expenditure of $100,000.

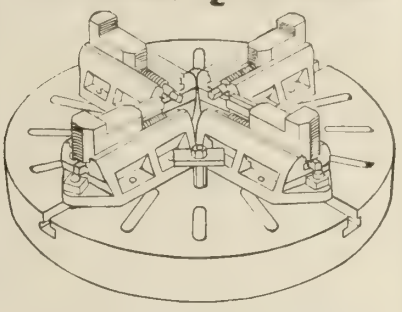
MEDICINE HAT, ALTA.—The Alberta Linseed Oil and Paint Co. will erect a plant here. It will be fireproof, of brick and cement, excepting elevators which shall be of the usual material.

TORONTO, ONT.—The Central Y.M.C.A. will erect a new building here at a cost of from $300,000 to $400,000. It will be of fireproof construction, with a steel frame, brick walls and fireproof floors and partitions.

EDMONTON, ALTA.—MacDougall & Secord contemplate the erection of a ten-storey business block on the corner of First and Jasper Streets. The date of construction has not been decided upon.

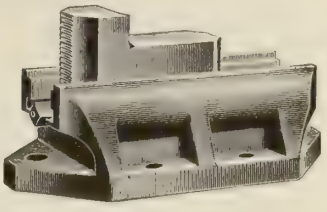
EDMONTON, ALTA.—Architect H. A. Magoon is preparing plans for a five-storey hotel to be built by J. B. Mercer, on present site of Grand Central Hotel. Cost about $100,000.

OTTAWA, ONT.—A new agricultural implement and machinery hall at the exhibition grounds will be built this year at a cost of $75,000.



REGINA, SASK.—Plans are ready for the new Donahue Block to be erected this spring on Eleventh Ave., at a cost of $100,000. It will be modern in every respect.

ORILLIA, ONT. -The Canada Refining and Smelting Co. will extend its plant here.



PRINCETON, B.C.—The British Columbia Portland Cement Co. is building a large plant here.

LUBRICATION AND SUPERHEAT

The greater use of superheated steam is making modern lubrication more difficult. You no doubt realize this yourself. In the event of trouble, however, we want to suggest to you

DIXON'S FLAKE GRAPHITE

which, unlike oil or grease, is entirely unaffected by any degree of superheat.

Engineers from all over the country write and tell us that Dixon's Flake Graphite solves their lubrication troubles experienced with superheated steam.

We would be glad to send you free trial sample by No. 223-C.

JOSEPH DIXON CRUCIBLE CO. - JERSEY CITY, N.J.

Paper Co. will make extensive improvements to its plant here.

CHATHAM, ONT.—The Western Bridge and Equipment Co. will build a large factory here.

PORT ARTHUR, ONT.—A new armory will be erected here in the spring at a cost of $125,000.

OTTAWA, ONT.—Tenders will soon be called on the new departmental block to be located here. The total cost will likely be about three and a half millions and big contractors all over the Dominion are making enquiries with a view of tendering.

VICTORIA, B.C.—L. W. Hargreaves has completed the plans for a five-storey hotel to be erected here. The building will be of reinforced concrete, and have elevators and a steam heating system.

SYDNEY, C.B.—R. L. Johnston, of St. John, has about completed arrangements for a large rolling mill plant here. New York capitalists are interested. He took options on two sites, and definite announcement of plans will be made later. The new company will construct a very large plant, having completed arrangements with the Dominion Steel Corporation for stock. They have secured from the Town Council a bonus of $50,000, with nominal water and tax.

REVELSTOKE, B.C.—The Dominion Saw Mills and Lumber Co., of Three Valley, and Revelstoke, B.C. have let a contract for the erection of a three-storey office building on Victoria Ave., here.

THREE RIVERS, QUE.—The Fres Falls Co. is pushing the construction of its pulp and paper mills at Cap de Madeline, near here.

PORT HOPE, ONT.—The Standard Ideal Co., manufacturers of enameled sanitary ware, are spending $100,000 on new construction.

WALKERVILLE, ONT.—The Canadian Bridge Co. is making a $100,000 addition to its works.

MERRITTON, ONT.—An addition of 40 x 60 ft. is being made to the works of the Wheel Company here.

PETERBOROUGH, ONT.—The addition the Canadian General Electric Co. is making to its works at Peterborough will be 125 x 274 ft. It is to be of brick and steel, and is to cost $100,000.

New Companies.

MONTREAL, QUE.—The Central Canada Iron & Steel Corporation capitalized at $15,000,000 has been incorporated.

VICTORIA, B.C.—The Western Laundry Machinery Co. has been registered.

MOOSE JAW, SASK.—The Moose Jaw Implement Co. has been incorporated to deal in farm implements. The firm is composed of A. H. Gamble, T. J. McCammon and W. C. Yeo, all of this city.

Trades Notes.

THREE RIVERS, P.Q.—The contract for the pulp machine for the Wayakamite Paper Co. has been let to the Jeffrey Mfg. Co., Montreal.

The Chapman Double Ball Bearing Co., Toronto, are now manufacturing ball bearings for the Tudhope, Reo and Ford Motor Companies. They have received the orders for bearings for the Canadian National Acme Mfg. Co. and Crown Laundry, Montreal, and new plants of Watson and Smith and Nasmith in Toronto.

WELLAND, ONT.—The Annual meeting of the Robertson Machinery Co. was held Jan. 13, when the following officers were elected: President, D. D. Hooker; vice-president, Blake L. Booth; secretary, J. H. Crow; directors, the above officers and Alex. Robertson and G. W. Sutherland.

TORONTO, ONT.—At the annual meeting of the shareholders of the Johnston Harvester Company, held at the head offices of the company in Batavia, N.Y., three directors of the Massey-Harris Company, viz.: Senator L. Melvin-Jones, Joseph N. Shenstone and Thomas Findley, were elected as directors. At a subsequent meeting of the directors, Senator L. Melvin-Jones was made president of the company, G. A. Farrall, vice president and general manager, L. D. Collins, treasurer and assistant general manager, and E. Atwater, secretary. Mr. Farrall, Mr. Collins and Mr. Atwater are residents of Batavia and are continuing in the active management of the company.

GALT, ONT.—The Stevens Co., manufacturers of machine tools have recently taken the agency for the Gronkvist Drill Chucks made in Katrineholm, Sweden.

Welland Board of Trade.

At the annual meeting of the Welland Board of Trade the following officers were elected:—David Ross, pres.; T. D. Cowper, vice-pres.; J. D. Payne, secretary; A. H. M. Hay, manager Bank of Nova Scotia, treasurer;

T. J. Dillon and F. A. Lount, auditors; B. J. McCormick, industrial commissioner; council, F. N. McConnell, H. F. Stoddard, H. L. Hatt, L. B. Duff, G. C. Brown and G. W. Hickey.

Canada Car & Foundry Co. Acquires Ontario Iron and Steel Plant.

Arrangements have been completed for the transfer of the Ontario Iron & Steel plant in Welland to the Canadian Car & Foundry Co., Montreal, which is a Canadian branch of the American Iron & Steel Co. The Ontario Iron and Steel Co. are completing a new $20,000 office building in Welland and additional improvements will be made. The Page-Hersey Works, managed by Mr. Mosley, is not included in the deal.

Dominion Iron & Steel Co. Coke Ovens.

Completing touches are being put upon the installation of Otto by-product coke ovens at the plant of the Dominion Iron & Steel Co., Sydney, N.S., and operations will be inaugurated within several months. The new plant consists of 120 ovens of the standard Otto type with a holding capacity of 13 tons of coal each. The product will be devoted to the requirements of the group of blast furnaces of the company. This is the second insallation of Otto ovens by the Dominion Iron and Steel Company, a plant of this type having been put in service there some years ago. Construction work on the present installation has been under way for the past 13 months and the completion of the plant within this period is regarded as a very satisfactory achievement considering the weather conditions that are confronted there by reason of the geographical location. The United Gas & Coke Co., Whitehall building, New York City, which controls the Otto rights, is building the plant.

Taylor & Arnold Open Winnipeg Office.

Taylor & Arnold, railway material and supplies, Montreal, have opened an office in the Scott Block, Main Street, Winnipeg, with G. C. Walker in charge, to look after all the company's western interest.

Incorporation of Robert W. Hunt & Co.

Robert W. Hunt and Co. have been incorporated under the Dominion Companies Act, with a capital of $50,000 and office at Montreal, to carry on the business, in all its branches, of civil, mechanical, mining and electrical engineers, analysts, metallurgists, surveyors, assayers, examiners and inspectors, to take over the Canadian business of Robert W. Hunt and Co., and also to acquire the business and carry out the contracts of the Standard Inspection Bureau.

Canada Motors, Limited.

Arrangements have been completed for the establishment of a new industry in Galt, known as Canada Motors. It will have a capital of $250,000. The following officers have been elected: president, George Dobbie; vice-president, A. M. Edwards; secretary, C. Jansen; managing director, D. R. Perry; treasurer, E. J. Getty. These, with Dr. MacKendrick, F. Stewart Scott, Dr. T. F. Campbell, all of Galt, and A. N. W. Clare, of Preston, will form the board of directors. The company have engaged temporary quarters until permanent buildings are erected.

Hamilton Facing Mill Co. Calendar.

Following their usual custom, the Hamilton Facing Mill Co., Hamilton, foundry outfitters and manufacturers of foundry facings and supplies are mailing to their friends a calendar for office or home decoration. It contains a reproduction of the famous painting "The Girl in Blue," by Wm. Thorne. The whole painting is a harmony of eloquent color for which the paintings of Wm. Thorne are notable.

Massey-Harris Co. Busy.

The Massey-Harris Co., Toronto, who have been working overtime for about two months have started a night gang and will be in full operation night and day.

New Bridge Co.

The National Bridge Co., has been incorporated with a capital of $1,000,000 and $3,000,000 bond issue. A large plant is being constructed at Longue Pointe, near Montreal. The steel work is up and the company will soon be operating. The new organization will have as its president, J. N. Greenshields; as vice-president, William Lyall, and the directorate will consist of Hon. Robt. Mackay, H. W. Beauclerk and B. M. Shepherd.

Large Steel Plant Near Vancouver.

Three hundred acres of land on the south side of the Fraser River, directly opposite Annacis Island, have just been secured by the Canadian-incorporated subsidiary company to the Western Steel Corporation as a site for a steel plant. The erection of huge blast furnaces and the expenditure of close on $2,000,000 in the construction of buildings and wharves and the installation of modern machinery is contemplated. In order to provide room for a large industrial city tributary to the steel works, private capitalists connected with the company have taken options on over 1,500 acres of adjoining property, and much of this is now being purchased outright. The location of the site which possesses over 1,700 feet of waterfrontage along the Fraser River with approaches both by land and water, has already been approved of by James A. Moore, president of the Western Steel Corporation, now operating a steel plant at Irondale, Wash. Among the Vancouver men interested in the proposition are R. P. McLennan, G. M. Gibbs, and S. G. Faulkner, all directors of the Canadian subsidiary company. Mr. McLennan confirmed the report that the purchase of 300 acres for a steel plant site had been approved by Mr. Moore.

Williams & Wilson, Montreal.

Williams & Wilson, Montreal, are turned into a joint stock company to take over the present machinery business of the firm. The capital is $200,000, and the incorporators are A. R. Williams, Toronto; F. C. Wilson, W. A. Wilson, M. B. Bronsbetter and E. Kingsland, salesman, of Montreal.

CATALOGUES.

Calendar.—Mussens, Montreal, are sending out a calendar, the figures occupying a space of 19 x 16 inches. They can, therefore, be seen from a long distance. Above the figures on the sheet for each month, are illustrations of machinery for which Mussens are selling agents, including machine tools, engines, air compressors, railroad and contractors' outfits, etc.

Friction Clutches.—The Carlyle Johnson Machine Co., Manchester, Conn., Catalogue "E," 1911, 35 pages, 4½ inches by 7 inches. An issue of 25,000. The catalogue is enclosed in a handsome cover of two-toned blue, with a clutch cut and company monogram embossed thereon, and is filled with attractive illustrations showing the Johnson Clutch, factory views, etc. The inside pages have an attractive blue border to correspond with the blue cover, this border being made up of reduced cuts of Johnson Friction Clutches, with the headings at the top, of the company name and address, as always used in their trade paper advertising. This catalogue is larger and more complete than previous ones, and deals almost exclusively with the driving of machinery through friction clutches, special attention being paid to the driving of machinery from line shafting, thus eliminating cross belting, countershafting, etc. There is special mention made of clutches for cut-off coupling work for use in connection with marine motors, as a one-way clutch for which work this type of clutch is particularly adapted. The lists are very complete, extending to clutch parts, which are numbered to correspond to the numbers indicating the parts on sectional views. Copies will be sent free to interested parties.

Calendar.—The B. Greening Wire Co. have issued a calendar for 1911 containing a bird's-eye view of the large plant in Hamilton, Ont. Half-tones are also given of Nathaniel Greening, who established the plant in Warrington, 1799; Benjamin Greening, who established the plant in Hamilton, 1859; S. O. Greening, president, 1877, and H. B. Greening, managing director. It is of interest to note that there are here represented four generations.

Machine Tools.—Eleventh addition of booklet, 28 pages, of lathes, planers, shapers and drills issued by the American Tool Works Co., Cincinnati.

Smooth-on Iron Paint.—12 page booklet from the Smooth-on Mfg. Co., 572 Communipaw Ave., Jersey City, N.J.

Browning Ditchers.—Descriptive catalogue, 9 x 12 inches, 32 pages from the Browning Engineering Co., Cleveland, describes their ditchers, giving dimensions of the devices and equipment such as buckets, booms, etc. The various operations are illustrated as well as their many uses such as wrecking cranes, locomotive cranes, electro-magnets, etc.

Gear Testing Machine.—Circular 821 from Adams Co., Dubuque, Iowa, describing the Farwell Gear Testing Machine.

Boiler Makers' Tools.—J. Faessler Mfg. Co., Moberly, Mo., have issued a neat catalogue No. 27, of 32 pages on coated stock, containing illustrations and descriptions of roller flue expanders, sectional beading expanders, flue cutters, patch bolt countersinking tools, etc.

Tapes and Rules.—The Lufkin Rule Co., Windsor, have issued catalogue No. 8, containing 96 pages, 6 x 9 inches. It is printed on coated paper, neatly bound and contains descriptions with illustrations of all styles of steel tapes, rules, squares, board sticks, etc. All classes of mechanics rules are described,

PRESS GUARD

This Guard is very simple, yet absolutely positive in its action, as the operator cannot trip the press while his fingers are in the danger zone. Also the press cannot repeat unless the Guard is down in front of dies, and then the operator cannot have his fingers in at the same time. The gate should be set so that it is down on base of die or bed of press when the latch of press releases. Then when the operator releases the treadle the gate will rise from 3 to 7 inches, according to requirements, leaving the front open to take out and put in work.

This Guard can be set so fine that anything 1-16 inch thick under the Guard gate will prevent the press from operating. Thus you can see it is utterly impossible for an operator to have his fingers between the dies and trip the machine at the same time.

Is not in the operator's way and does not interfere with the output of press; works on all kinds of presses, back-geared, large or small.

Note the rigid connection between Treadle, Guard and Latch.

These Guards are already installed in a number of large manufacturing plants and are giving every satisfaction.

We also manufacture guards for woodworking machines.

Write us for circular matter.

Don't Stop at Merely Wishing

A natural wish of every power plant proprietor and engineer is for an absolutely reliable belt.

And this wish can be quickly realized by the purchase of

"Climax" Leather Belting

This is the belt that doesn't stretch or slip or cling too tight; the belt that will stand hard service with credit to the maker and enduring satisfaction to its user.

There is very little real competition to CLIMAX BELTING---it is so good as to be in a class by itself --- Canada's standard line of high grade leather belting.

When you buy CLIMAX you buy the utmost value and reliability in leather belting.

Sadler & Haworth

Montreal, 511 William St.
Toronto, 27 Melinda St.
St. John, N.B., 89 Prince William St.
Winnipeg, 244 Princess St.
Vancouver, B.C. 217 Columbia Ave.

including folding pocket rules, machine divided rules, etc.

Chains.—Circular No. 7, from Jones & Glassco, Montreal agents for Renold block and roller chains.

Calendar.—For 1911, from American Tool Works Co., Cincinnati. At the top of the sheet, for each month is a half-tone of one of the various types of machine tools manufactured by this company.

Time Recorders.—Sample cards and sheets from W. A. Wood, 40 St. George St., Montreal, manufacturers of "Globe" time recorders.

Calendar.—The I.C.R. have issued a 1911 calendar. The emblematic moose head which is usually a feature of the I.C.R. literature and calendars, appears prominently on the calendar.

Cranes.—Catalogue 82 from Whiting Foundry Equipment Co., Harvey, Ill., 40 pages. The features of Whitney Standard Cranes are shown with a large number of typical installations. These include railroad shops, machine shops generally, power plants, etc. The names of some of the principal customers are also given.

Cranes.—Catalogue No. 25 of 56 pages from the Northern Engineering Works, Detroit, Mich. Several types of cranes are described and illustrated. Installations in machine shops, foundries, yards, car shops, power plants, etc., are given, showing many applications of the various types of cranes.

Book Review.

A Pocketbook of Mechanical Engineering.—By Charles M. Sames, B.Sc. Fourth edition. Bound in flexible leather. Size, 4 x 6⅝ in.; pages, 220; 42 illustrations. Price, $2. Published by the author, 542 Bramhall Avenue, Jersey City, N.J. This book contains a collection of tables, data, formulas and examples, comprising the greater part of the reference information usually required by mechanical engineers and students, condensed into a volume, the dimensions of which are small enough to e conveniently carried in the pocket. In preparing this last edition, new matter has been incorporated to bring the work thoroughly up-to-date. Among these added subjects are new alloys and alloy steels, critical speed of shafts, new steam tables, formulas dealing with saturated and superheated steam, steam turbines, electric drive and the power required for machine tools and cooling towers. Besides these subjects new data have been added at a number of points in the text. The book is a useful one to draftsmen and mechanical men generally.

Shop Kinks. By Robert Grimshaw. Bound in cloth. Size 6 x 7½ in. Pages 393; illustrations 224. Published by the Norman W. Henley Publishing Co., 132 Nassau Street, New York. Price $2.50. This is the fifth edition of a book that shows special ways of doing work, as it is done in a number of leading shops in America and Europe. The work is the outcome of a notebook started by the author about 30 years ago and contains items written by the author and others for technical journals and also material gathered from visits to shops or based on data contributed by leading machine tool builders and users. As far as possible the effort has been made to group items of the same nature together, and the finding of them is rendered easy by an extensive alphabetical index.

Freight Train Resistance: Its Relation to Car Weight.—By Edward C. Schmidt, has just been issued as Bulletin No. 43 of the Engineering Experiment Station of the University of Illinois. This bulletin presents the results of tests made upon freight trains to determine their resistance. The results show that the average weight of the cars composing the trains exerts upon train resistance an even greater influence than is exerted by variations in train speed. Copies of Bulletin No. 43 may be obtained gratis upon application to W. F. M. Goss, Director of the Engineering Experiment Station, University of Illinois, Urbana, Illinois.

We manufacture all kinds of Pumping Machinery, Condensers, Travelling Cranes, etc.

Short Cuts in Machine Shop Practice

Hundreds of parts such as axles, bushings, collars, ball and roller bearings, cutting punches, hollow drills, piston rods and shafts, lathe spindles and sockets, which formerly had to be bored from solid steel, are now made in up-to-date shops and factories by simply cutting Shelby Seamless Steel Tubes to length.

Shelby Seamless Steel Tubing is made in hundreds of sizes and gauges, in round, square, rectangular, hexagonal, octagonal, oval or almost any other section. It can be bent, coiled, flanged, expanded, swaged or plated, and it solves most of the hard mechanical problems at once.

We can make immediate shipments of 350 sizes from our stocks at Montreal and Toronto. Write for stock list, prices and information to

Shelby Seamless Steel Tubing

A DOUBLE-SERVICE LATHE

24-46 in. Extension Gap Lathe

PRACTICALLY TWO LATHES IN ONE

Because while it has ample power and strength to turn the full swing of the gap and the full length of the extension, it will handle ordinary work as economically as a smaller tool. Hence, while giving to the shop the capacity to do jobs that would be impossible on ordinary lathes, the tool can be kept profitably employed all the time. In the compactness of its general design, its range and capacity, as well as in its strictly modern, up-to-date construction, it shows a marked improvement over extension gap lathes as commonly built.

It has carbon steel head spindle, ground to size, bronze spindle bearings carefully scraped and fitted, cut-away tailstock, with provision for setting off center for taper work, carriage extended for turning full swing of lathe, apron of double plate type, tongued and grooved into the carriage, with gears and studs of ample proportions. Every detail has been studied out with the utmost care, the tool representing as a whole the latest and best in design, material and workmanship.

LET US SHOW YOU HOW IT WILL INCREASE THE MONEY EARNING POWER OF YOUR PLANT.

BROWNING

How many mill owners have warded off the thought of buying a Locomotive Crane for handling of their logs and dimension timbers, thinking the equipment a LUXURY? Later you would be surprised at the great number of these same mill owners who, after seeing their smaller competitor install a "BROWNING," have investigated and found the outfit a NECESSITY and a money-saver instead.

A Double Economy

Carborundum Grinding Wheels are not only the fastest cutting but also the longest lasting grinding wheels on earth. For instance:

An Indianapolis concern is using Carborundum Wheels in grinding cast iron piston rings. Each wheel turns out 450 to 500 rings an hour, removing .010 inches stock. And yet, notwithstanding the speed at which the wheels cut, the micrometer shows that 50 rings are ground before there is any perceptible wheel loss. Result —A Double Economy.

We will be glad to show you what Carborundum is doing in other lines of grinding—if you will write.

MISCELLANEOUS.

A BOOK-KEEPING STAFF IN ITSELF — doing the work with machine-precision and accuracy, the National Cash Register. Write us for demonstration literature. National Cash Register Co., 285 Yonge St., Toronto.

ACCURATE COST KEEPING IS EASY if you have a Dey Cost Keeper. It automatically records actual time spent on each operation down to the decimal fraction of an hour. Several operations of jobs can be recorded on one card. For small firms we recommend this as an excellent combination—employees' time register and cost keeper. Whether you employ a few or hundreds of hands, we can supply you with a machine suited to your requirements. Write for catalog. International Time Recording Company of Canada, Ltd. Office and factory, 29 Alice Street, Toronto.

COPELAND-CHATTERSON SYSTEMS — Short, simple. Adapted to all classes of business. Copeland-Chatterson-Crain, Ltd., Toronto and Ottawa. (tf)

COUNTER CHECK BOOKS — Write us to-day for samples. We are manufacturers of the famous SURETY NON-SMUT duplicating and triplicating Counter Check Books, and Single Carbon Pads in all varieties. Dominion Register Co., Ltd., Toronto.

DOUBLE YOUR FLOOR SPACE. An Otis-Fensom hand-power elevator will double your floor space, enable you to use that upper floor either as stock room or as extra selling space, at the same time increasing space on your ground floor. Costs only $70. Write for catalogue "B." The Otis-Fensom Elevator Co., Traders Bank Building, Toronto. (tf)

DURING 1910 the MONARCH displaced hundreds of Typewriters of all makes. In 1911 we anticipate a still greater demand. We have cut down the allowance on these second-hand machines and consequently can sell them cheaper to you. They are carefully rebuilt and are guaranteed to give satisfaction or your money back. If you want a good, strong, clean working Typewriter at a mere fraction of the original cost, write us for catalogue. THE MONARCH TYPEWRITER CO., Ltd., 46 Adelaide Street West, Toronto, Ont.

EGRY business systems are devised to suit every department of every business. They are labor and time savers. Produce results up to the requirements of merchants and manufacturers. Inquire from our nearest office. Egry Register Co., Dayton, Ohio; 123 Bay St., Toronto; 258½ Portage Ave., Winnipeg; 308 Richards St., Vancouver.

ELLIOTT-FISHER STANDARD WRITING-ADDING MACHINES make toil easier. Elliot, Fisher, Limited, Room 314, Stair Building-Toronto.

FIRE INSURANCE. Insure in the HARTFORD. Agencies everywhere in Canada. (tf)

GET THE BUSINESS—Increase your sales—Use Multigraph typewritten letters. The Multigraph does absolutely every form of printing. Saves you 25 p.c. to 75 p.c. of your printing bill. Multigraph your office forms, letterheads, circular letters. Write us. American Multigraph Sales Co., Ltd., 129 Bay Street, Toronto.

MISCELLANEOUS.

IF YOU have been afflicted with one of those fountain pens that won't write when you want it to, or leaks when you don't want it to, give it away to one of your poor relations and buy a Moore Non-Leakable Fountain Pen and you will be happy. Consult your stationer. W. J. Gage & Co., Toronto, sole agents for Canada.

INDISPENSABLE in office, store, home—Canadian Almanac, 1911—a National Directory. Complete classified information on every subject of Dominion interest. Full Postage, Customs, Banking, Insurance, Legal, Educational, Newspaper, Army, Clerical, Governmental, Particulars of leading Institutions and Societies. Paper Covers, 60c. Cloth, Leather Back, 75c. All stationers, or sent postpaid on receipt of price by The Copp-Clark Co., Ltd., Toronto.

KAY'S FURNITURE CATALOGUE No. 306 contains 160 pages of fine half-tone engravings of newest designs in Carpets, Rugs, Furniture, Draperies, Wall Papers and Pottery with Cash prices. Write for a copy—it's free. John Kay Company, Ltd., 36 King St. West, Toronto.

MODERN FIREPROOF CONSTRUCTION—Our system of reinforced concrete work, as successfully used in many of Canada's largest buildings, gives better results at lower cost. "A strong statement," you will say. Write us and let us prove our claims. That's fair. Leach Concrete Co., Ltd., 100 King St. West, Toronto. (tf)

MR BUSINESS MAN, are you progressive? It's up to you to test "Consolidated," our new process carbon paper. Because it costs less. Soft finish, without smutting, and clear, permanent copies. Write for sample sheets and prices. "Consolidated." Stratford, Ont.

PENS—The very best Pens made are those manufactured by William Mitchell Pens, Limited, London, England. W. J. Gage & Co., Limited, Toronto, are sole agents for Canada. Ask your stationer for a 25c. assorted box of Mitchell's Pens and find the pen to suit you.

"SYSTEMS" stand for all that is best in loose-leaf binders and supplies, letter-heads, statements and in fact your office stationery of every description. Send us samples of what you are using—we will send you prices that will interest you. Business Systems, Limited, Manufacturing Stationers, Toronto. (tf)

THE "Kalamazoo" Loose Leaf Binder is the only binder that will hold just as many sheets as you actually require and no more. The back is flexible, writing surface flat, alignment perfect. No exposed metal parts or complicated mechanism. Write for booklet. Warwick Bros. & Rutter, Ltd., King and Spadina, Toronto.

THE METAL REQUIRED in a Modern Concrete Building. Our special facilities enable us to produce at minimum cost Concrete Reinforcements, Fenestra Steel Sash, Automatic Fire Shutters and Steelcrete Metal Lath. Complete stock, quick delivery. Before deciding write us for catalogue and prices. Expanded Metal and Fireproofing Co., Ltd., Fraser Ave., Toronto. (tf)

WAREHOUSE AND FACTORY HEATING SYSTEMS. Taylor-Forbes Company, Limited. Supplied by the trade throughout Canada. (tf)

SHOP AGENT WANTED.

WE want an agent in every machine shop in Canada where fifteen or more men are employed, to take subscriptions to this Journal. Subscriptions are easily obtained and the work can be carried on by giving a few minutes to it in the noon hour. Liberal commissions allowed both for new subscriptions and for renewals. Write for terms. Agents' Dept. CANADIAN MACHINERY, 143-149 University Ave., Toronto.

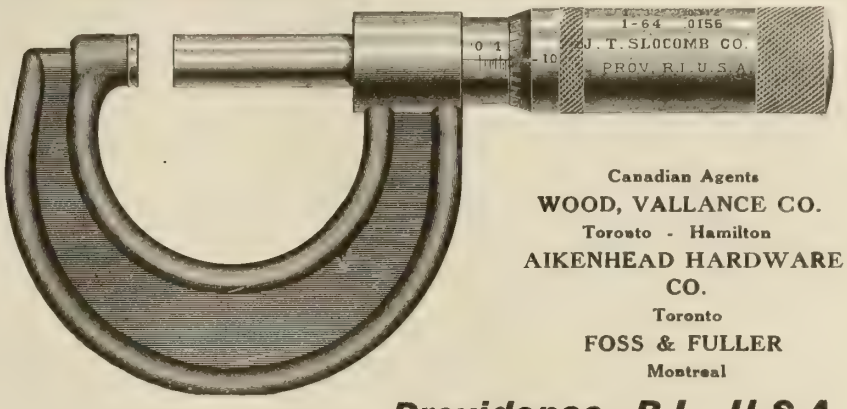
Accuracy Before Everything



is the motto of all first class mechanics—the men with nice jobs in first class shops. And most of them use

"SLOCOMB"

Micrometer Calipers

Simply because they combine with highest accuracy, best adjustments, great durability and are most handily used.

Ask your dealer to show you, and note the table of decimal equivalents on the thimble, consisting of 8ths, 16ths, and 32nds---a brand new feature of great value. This handy table is in all sizes from 1 in. to 24 in.

Cable Address: "CUPOLA," Keighley.

A GOLD MINE

SAVE YOUR IRON

SLY'S PATENT IRON CINDER MILL

Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the coke contained in your cupola dump, and gangway scrapings. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

THE W. W. SLY MFG. CO., CLEVELAND, O.

The use of a good core sand binder will lower several of your cost items.

Glutrin is the best core sand binder.

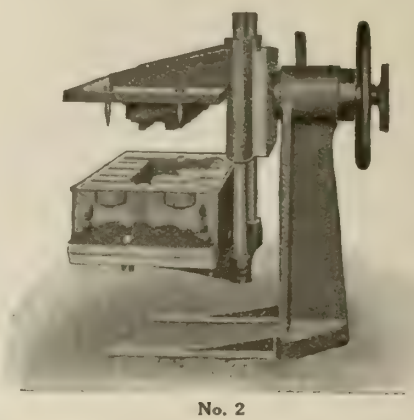
Crucibles of Quality



Grimes Roll-Over Molding Machine

No. 1

This is a simple, standard machine, requiring small floor space.

It is perfectly balanced, requiring no counter-balancing mechanism, as centre of gravity is centre of rotation.

No. 2

By means of small hand wheel shown in cut, one man can turn largest flask smoothly and without jerk.

Pattern is drawn by absolutely straight gravity drop.

This machine is adjustable for deep flasks and can readily take care of flask 24 in. x 36 in. and 4 to 12 in. in depth, with maximum pattern draft of 12 in.

Positive adjustable pins at four corners of clamping device, Fig 2, compensate for unevenness of floor boards.

PRICE, f.o.b. cars Windsor, $125.00

HIGH GRADE CASTINGS are not made with low grade materials. Think this over when you see a poorly finished casting in your cleaning room, and remember, if you please, if you wisb to place the pattern in the high grade class, our No. 48 Plumbago will do it, also that the saving in cleaning room expense would pay for three times the necessary No. 48 Plumbago to have made it high grade.

Another vital point is that you have a core wash which will peel clean and not run before the metal. Try our Eureka Blacking, the best core wash on the market.

THE SELECTION OF FIRE BRICKS

Sole manufacturers of KING Fuel Oil Furnaces for all heating and melting purposes

Fire Bricks are a necessary item of expense and, as such, should be given careful consideration. This expense is only kept on a minimum basis by using the most suitable fire brick to meet the exact conditions of service.

The purchase price of Fire Bricks does not indicate their cost.

It is the life of the Fire Brick which demonstrates whether you are getting full value for the money invested.

In addition to being required to withstand heat, Fire Bricks are frequently subjected to one or more of the following conditions:

1st. Chemical action of powerful fluxes and slags.

2nd. Reducing action of gases.

3rd. Sudden heating and cooling with wide temperature variations.

4th. Pressure and grinding action.

5th. Abrasion.

6th. Cutting and impinging flame.

7th. Combination of one or more of the above with heat.

No matter what your needs are, we have a brick which will give you satisfaction.

Our technical department is ready at all times to offer suggestions which will eliminate your fire brick troubles.

Protect yourself against tedious delays and costly experiments by buying your fire bricks from us—who know this business from A to Z.

The best known brands on the market to-day are our WOODLAND, H.W. SPECIAL, MUNRO, BONNYBRIDGE, KIRKWOOD.

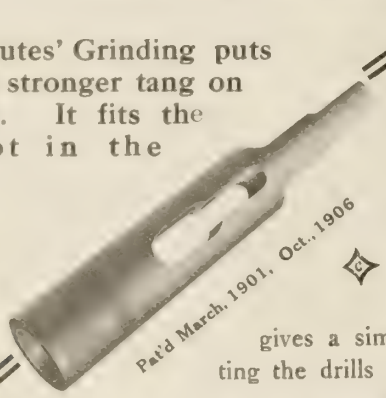
"MORSE"



Twist Drills

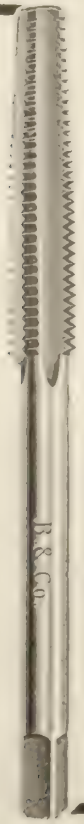
will do your work as you want it done.

MORSE TWIST DRILL & MACHINE CO., New Bedford, Mass., U.S.A.

Our goods are handled by—Rice Lewis & Son, Ltd., Toronto; Aikenhead Hardware Co., Ltd., Toronto; Frothingham & Workman, Montreal; Mechanics Supply Co., Quebec.

Three Minutes' Grinding puts a new and stronger tang on the shank. It fits the lower slot in the socket.

What Do Your Twisted-Off Tangs Cost?



Keep account for a time of the new drills used to replace those thrown into the scrap heap because of twisted-off tangs, and you will see. These scrapped drills are all right in every other respect.

The "PERFECT" Double-Tang Socket

gives a simple, effective, and inexpensive means of eliminating this cost and putting the drills back in money-earning shape. **Write for Folder A.**

The CLEVELAND Twist Drill Co. CLEVELAND Chicago New York

BUTTERFIELD'S
Taps, Dies and Reamers

have found favour with the best mechanics in every part of the Dominion because they are accurate tools, thoroughly tested, reliable and made to wear.

The special hardening and tempering is responsible in a large measure, for the excellence of these tools, in the manufacture of which only the first quality materials and highest skilled labour are employed.

Write us to-day for details and prices.

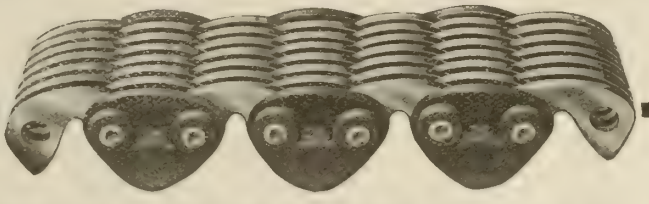
Power Talk No. 3—

That New Power Plant

Will be installed with an eye to getting the best results from every ton of coal.

Your power transmission equipment should be bought with the same care.

The difference between the cost of power at your engine or motor and at your machine averages from 20% to 70%.



This is wasted in friction.

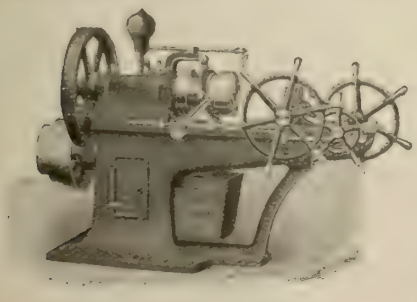
Chapman Double Ball Bearings are guaranteed to save 75% of this shaft friction and 95% of lubrication over any type of self oiling bearings.

They are now installed in over 1,000 Canadian factories. Send us a rough sketch of your shafting layout and we will advise you as to the amount of power that can be saved and the cost of installing Ball Bearings.

The Chapman Double Ball Bearing Co. of Canada, Limited

347 SORAUREN AVENUE, TORONTO, CANADA

COVENTRY "NOISELESS" CHAINS



are in very many cases preferable to any other form of power transmission. Positive speed ratio—low journal pressure—high efficiency—silence—and the ability to run satisfactorily in damp or heated atmosphere, are rapidly bringing "COVENTRY" Noiseless Chain Drives into favor in factories and machine shops, on automobiles, motor trucks and aeroplanes—in fact almost everywhere that power is transmitted.

We will be glad to give you full information and suggestions for applying "COVENTRY" Noiseless Chain Drives to your power transmission problems. Write us for the "COVENTRY" Catalogue.

The Small Knurled Wheel Provides for Quick Readjustments

B. & S. SPEED INDICATOR

This indicator has overcome one of the most serious drawbacks to the older styles of such tools---the tedious turning back of the rotating disc by hand after a reading has been obtained.

This quick adjustment is an exclusive B. & S. feature secured by means of the small knurled wheel on the side of the case

Among the other features which should be mentioned are the following: It registers on either side, the dial on front determining the velocity of shafts and spindles running in one direction, and the reverse side the speed of those running in the opposite; it is small, light and convenient to handle.

Send for a Special Folder, mailed on application

Brown & Sharpe Mfg. Co.

Providence, R.I., U.S.A.

CANADIAN FOUNDRYMAN BUYERS' DIRECTORY

To Our Readers—Use this directory when seeking to buy any foundry or pattern-shop equipment. You will often get information that will save you money.

To Our Advertisers—Send in your name for insertion under the heading of the lines you make or sell.

To Non-Advertisers—A nominal rate of $1 per line a year is charged non-advertisers.

We are introducing a new line in

GRINDING WHEELS:

Dominion Abrasive Wheels

These wheels are made by the vitrified process, recognized as the BEST in the world. We use the very best emery and artificial abrasives combined with a special bond of our own.

We produce a fast cutting wheel, which will not draw the temper of your tools and which we guarantee to be thoroughly satisfactory.

WRITE US FOR PARTICULARS.

THIS NEW GAP LATHE
WILL INCREASE YOUR PROFITS

INCREASED speed and efficiency means increased profits. This new gap lathe increases speed and efficiency for the following reasons:—The extra strong gap gives absolute rigidity. The construction of the carriage and apron is such that they will not spring under the most severe strain. Headstock will not chatter. Tailstock fitted with quick acting locking device. Tailstock adjusted from the top. Friction safety feeds give quick changes of thread. Eighteen distinct spindle speeds by double back gears. Specially graduated dial on the gear box. Adjustable to thousandth of an inch both ways by graduated compound rest. Ring oilers give perfect self lubrication. Greatest strength, accuracy, solidity and wear. Full equipment with each lathe.

Headstock construction prevents chattering, and deep oil chambers fitted with ring oilers make spindles and bearings self-oiling and always well lubricated.

Tailstock of a special type, and sleeve is clamped by a quick acting locking device. Tailstock is secured to bed by bolts adjusted from the top where they are easily accessible.

Bed, non-springing and webbed, and braced to secure rigidity.

Gap, vibration absolutely prevented by use of brace supports to carriage.

Spindle, high carbon hammered steel in solid chilled cast iron bearings, accurately fitted and self oiling.

Carriage and Apron, non-springing under severest strain, full "V" bearings and flat bearings in addition on front ways.

Double Back Gears give eighteen distinct spindle speeds, suiting lathe to work on widely different diameters.

Compound Rest, with graduated base, accurately fitted taper gibs, end adjusted. Screws in both rest and cross slide read to thousandths.

Friction, Safety Feeds, screw and rod feeds cannot be both engaged at the same time. Quick changes of 1¼, 2½ and 5 times thread being cut.

Gears and Racks, cut from solid and steel where necessary.

Screw Cutting, full range of commercial threads provided for.

Equipment, Compound rest, steady rest, follow rest, large and small face plates, wrenches, two-speed, friction countershaft furnished with each lathe.

Accuracy, Strength, Solidity, Wear. These are the paramount features behind all McDougall Machines. Made **to meet extreme demands.**

A Machine for Manufacturing

And it looks it—not a frail or weak part in the entire construction, It is a machine meant for business—to do business on a manufacturing basis—an economy basis.

It is a business builder, not only on account of its wonderful latitude—its flexibility and adaptability—but on account of its stability—its staying qualities—its continued accuracy—its wonderful control and ease of manipulation—its duplicate manufacturing that does away with all bench work. Turns out every piece of work fully finished—and interchangeable—ready to be assembled—castings, forgings or rod work.

And the tool outfit—once complete—always complete, to meet any manufacturing demands. That is

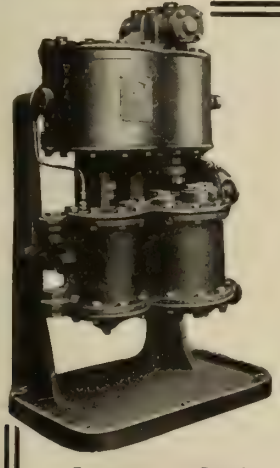
S & S AUTOMATIC Gear Hobbing Machines

One of our customers writes us:

"We were using six automatic gear cutters in our works, but since putting in your machine we have been able to turn out as much work on your machine as on any three of the others and with greater accuracy."



This great output and accuracy are not only due to the Hobbing System, but also to the rigid construction and right distribution of weight in our machine The patented features of our machine place it in a class by itself.

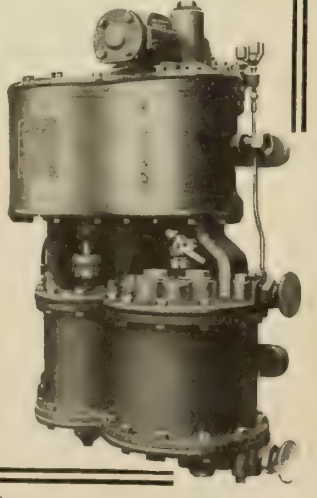
Compressor on Stand



Westinghouse

$10\frac{1}{2}$" Cross-Compound Air Compressor

For Industrial Work

The Westinghouse 10½" Cross-Compound Compressor at a normal speed of 13 strokes per minute, operated on a steam pressure of 100 lbs., working against 80 lbs. air pressure, has a displacement capacity of 150 cubic feet of free air per minute.

It is a compact, self-contained unit, compounding both air and steam, thereby securing a very high efficiency with a low steam consumption per 100 cubic feet of air compressed.

Important Announcement

By special arrangement with the R. K. Le Blond Machine Tool Co., of Cincinnati, we are now enabled to offer for the first time in Canadian Machine Tool History, Lathes made in Canada from designs based on the wealth of experience afforded by the United States market, the greatest machine tool market in the world.

By this arrangement we have obtained not alone the designs, but also the jigs and other fixtures which make for accuracy, interchangeability, and produce unequalled workmanship at a minimum of cost.

The above Lathes represent the very last word in Lathe Construction. Powerful, yet accurate and easily handled—designed for getting the greatest amount of work with a minimum of expenditure of energy on the part of the operator.

Details of construction will appear from time to time in our advertisements.

Garvin Double-Geared Dividing Heads

For Accuracy and Fine Work

Appreciated most by those who have experimented with the other kind.

Heads are put through the most rigid inspection before leaving shop and have been highly commended by users for their accuracy and rigidity under the most exacting cuts. The heads

Divide all numbers to . . .	150
Numbers divisible by 2 and 5 to	300
Numbers divisible by 3 to . .	360

Dividing mechanism undisturbed. Accuracy maintained when changing for quick indexism. As may be seen by sectional cut, the horizontal and vertical positions can be instantly located. Note the spindle with a ground taper bearing its entire length, being solid with the dividing gear, which is of large diameter and is located as near the work as possible. Wedge take-up for wear in dividing gear. Many other valuable features. Manufactured in three sizes, 10, 12, and 14 inches, and are part of the equipment furnished with our Universal Milling Machines.

You Pay for the Bullard Vertical Turret Lathe Whether You Buy It or Not

And the longer you wait, the more you pay.

IF YOU ARE NOT USING THIS MACHINE YOU PAY FOR IT, NEVERTHELESS, WITH THE MONEY LOST BY YOUR PRESENT METHODS OF PRODUCTION OF ALL FACE PLATE WORK WITHIN THE RANGE OF THE VERTICAL TURRET LATHE.

This loss is caused principally by wasted time.

The fundamental principle of the Vertical Turret Lathe is the "**elimination of wasted time.**"

Time between cuts is reduced by centralized control of the operation of the whole machine, as well as by rapid power traverse of all parts.

With both a Turret and a Side head, machining of several surfaces at once is possible — ***Multi-Cutting.*** And all the tools needed for a series of operations are held in instant readiness.

In all, every possible moment of the machine's and the operator's time is utilized and made efficient.

Ask for Treatise on Face Plate Work C-15.

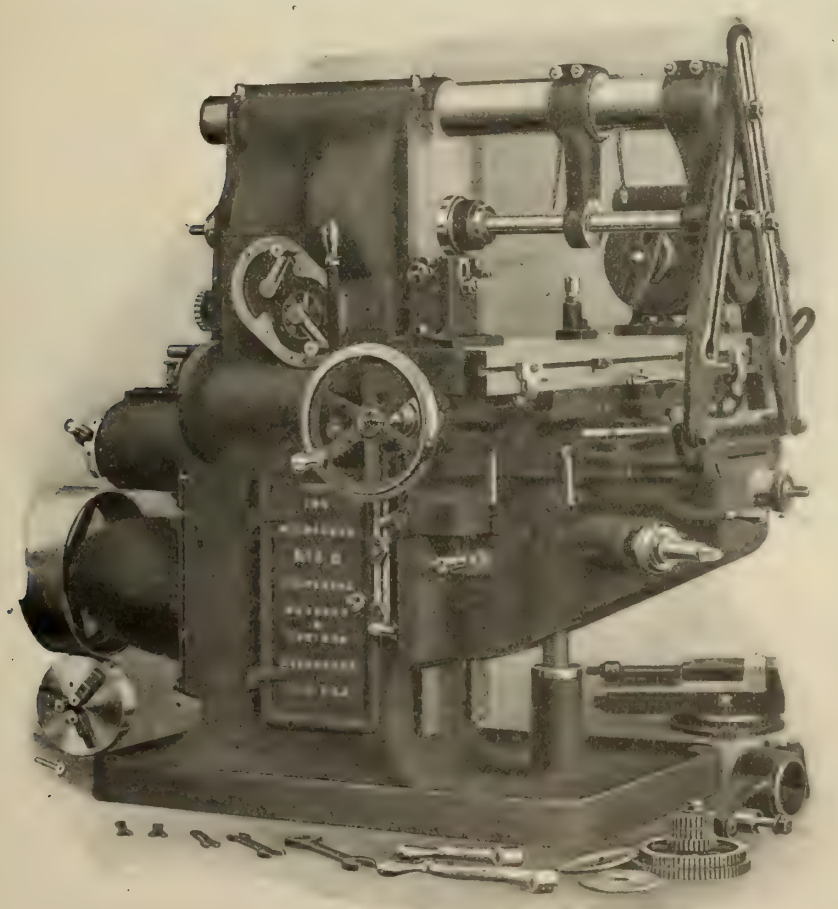
Cincinnati Handiness

WHEN you have a job of end or face milling to do on a Horizontal Miller, don't you find it hard to operate the feed lever and at the same time keep your eye on the cutter? That's because the machines you are using can be operated from only one place. Our new High Power Machines have an additional feed lever at the side of the knee.

The operator can stand close up to his work, with the cutter in full view, and control the machine from this position.

With this one lever he can operate and reverse table, cross or vertical feeds.

The main starting lever is immediately in front of him and the speed and feed changers are at his elbow, so that the entire machine is under complete control from here.



ASK FOR THE CATALOG.

The Cincinnati Milling Machine Company

Milling Specialists

CINCINNATI, OHIO, U.S.A.

Canadian Agent—H. W. PETRIE, Ltd., Toronto, Montreal and Vancouver.

THE MILWAUKEE

No. 3B Universal Miller

is one of a line of Plain and Universal Milling Machines for heavy duty service having great weight and structural strength in comparison with range. Powerful drive through single pulley as shown or at right-angles. Electric drive applied without difficulty at any time. All gears and bearings automatically flooded with oil. Every machine equipped with pump for cooling and lubricating the cutters and with means provided for returning the cutting lubricant to its reservoir. Wide table for jig work with ample bearings for maintained accuracy. Accurate screws with sensitive graduated adjustments—all adjusting and feed screws have ball thrust bearings. Dividing wheel double the size usually used—accuracy equal to the best.

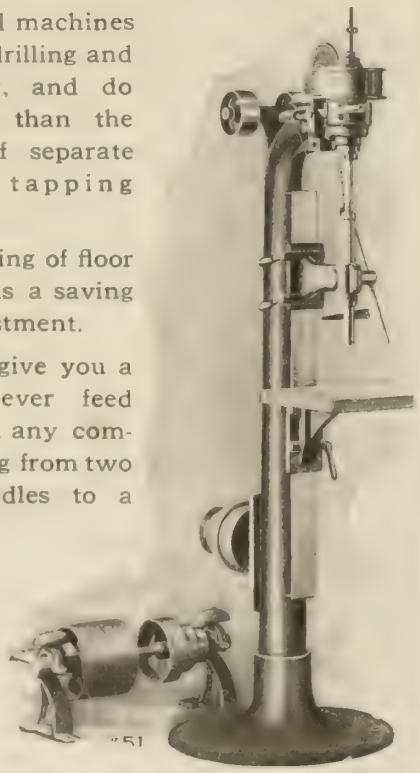
Machinery Always Busy

These three words express one of the essential requirements of a profitable machine shop business—machinery that is always earning its keep.



There is no need for you to tie up capital in separate drilling and tapping machines when you do not expect to use each machine constantly. It will pay you better to install a

"Barr" Combined
Drilling & Tapping Machine

Barr combined machines will do better drilling and better tapping, and do them quicker, than the general run of separate drilling and tapping machines.

It means a saving of floor space as well as a saving of capital investment.

We can also give you a power feed, lever feed and tappers in any combination having from two to seven spindles to a machine.

24 inch Swing Standard Lathe

Like all NEW HAVEN TOOLS, it is conspicuous for its accuracy, reliability and durability, and each machine is thoroughly tested before it leaves our shops. Guaranteed unreservedly. Write for detailed specifications and illustrated catalogue.

New Haven Manufacturing Company

NEW HAVEN : CONN : U.S.A

OUR
No. 264 SELF-FEED RIP SAW

Embodies in its construction all features that are necessary for the satisfactory handling of light or heavy material.

No. 264 Self-Feed Rip Saw.

It is equally efficient in ripping SHORT or LONG Stock. Both the in-feeding and out-feeding roll may be adjusted close to the saw, permitting short stock to be fed without trouble.

The Feed Rolls may be instantly raised, converting it into a hand-feed machine when desired.

The table raises and lowers to accommodate different thicknesses of stock.

Capacity—Rips 4 in. thick with a 16 in. saw, and 8 in. with a 24in. blade. Takes 19in. between saw and fence.

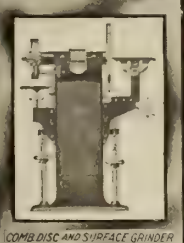
The Quick Feed and Thread Changes on CHAMPION LATHES

16-in. Quick Change Lathe.

Are so easily made that they are in striking contrast to the many so-called quick-change devices which wear the patience of the operator in hauling, pulling and jerking levers to shift gears, that there is little wonder lathe hands don't take advantage of feed changes, but instead run on practically one feed



These changes on the **Champion** are so simple and comprehensive that the operator on learning how easily and quickly they can be made, takes advantage of the correct feeds and speeds without fear of complications.

Write for Our Catalogue of 10-12-14-16 and 18-inch Lathes; Quick Change or New Standard, with or without Taper Attachment, Draw-in Attachment, Turrets, etc.

SHELBY SEAMLESS STEEL TUBING

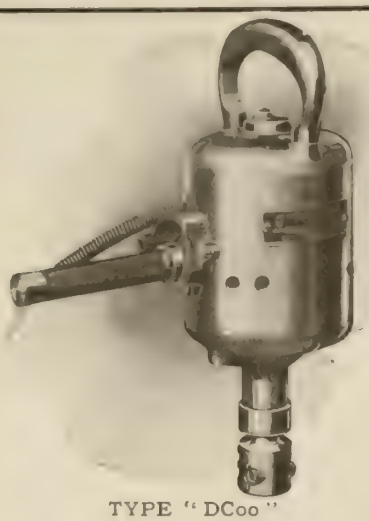
This photograph shows a remarkable coil of Shelby Seamless Steam Tubing turned out recently for La Cie de Gaz de Lachine, Lachine.

The diameter of the coil is nearly seven feet, and the length about twelve feet. It is made up of twenty circular sections of tubing 3⅞ inches in outside diameter, with 9/16 inch walls—a total of 400 feet of tubing,

The seamless steel cylinder shown resting on the trestles is 9 feet long, 9⅝ inches outside diameter, with walls 1⅜ inches thick, and a capacity of 3,800 cubic inches. Test pressure 6 tons per square inch.

We show this coil and cylinder because they give an idea of the out-of-the-ordinary work which we can turn out in Shelby Steel Tubing. Shelby Tubing can be

Bent, Flanged, Expanded, Tapered, Upset, Spun, Case-hardened, Machined infinitely, Applied manifoldly.



We are prepared to handle all kinds of special work in Seamless Steel Tubing, or to make Seamless Steel Cylinders in any size or capacity. Write us about your requirements. We shall be glad to suggest ways and means of meeting them economically and to the best advantage.

ELMIRA, N.Y.

Riveting by Lightning

NO RIVETS USED.

You have heard of lightning melting a piece of metal.

That is what's done in a Spot Welder—only the lightning is tamed and harnessed. So tame that you can't feel it (only three to five volts), and harnessed to a machine that a boy or girl can operate with absolute safety. And FAST—well you have heard of "greased" lightning. That's the brand.

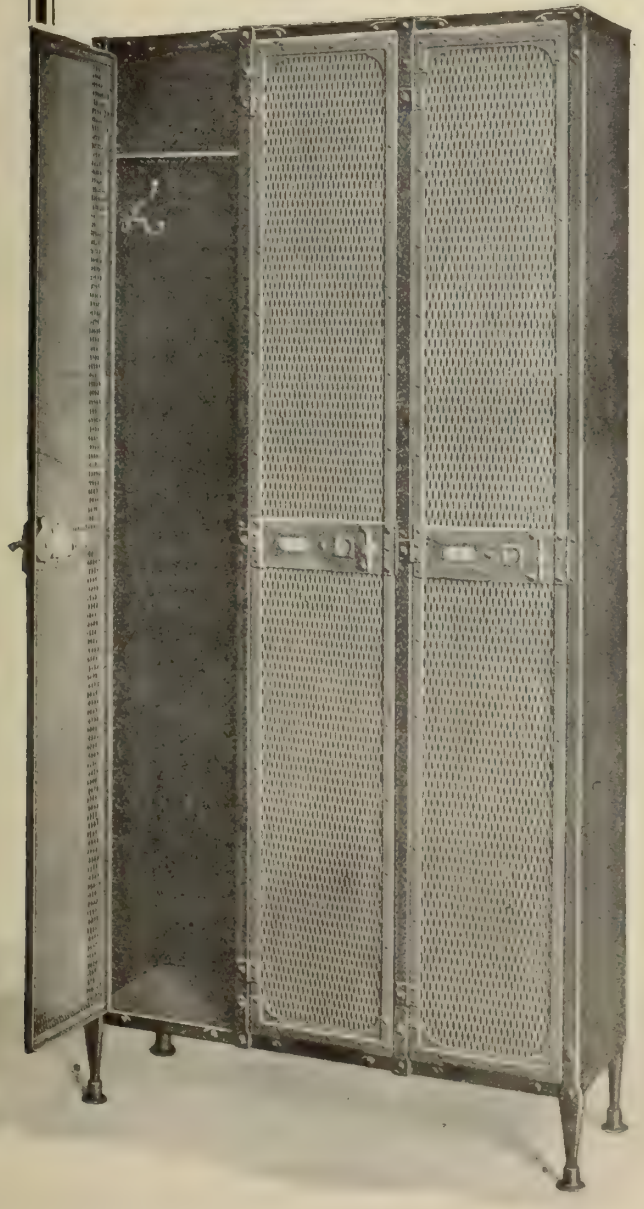
One "Spot" will weld two pieces of No. 18 gauge sheet steel together tighter than two rivets. The same machine will weld No. 10 gauge or No. 28 gauge equally as well.

Spot Welded—so called because the small point in the metal the size of a rivet is melted—fused together at the spot where the copper dies touch the metal.

No holes to punch no rivets to use—no projections to raise—no time wasted.

Our new catalog tells about spot and butt welders, and its yours for the asking.

No Lease. No Royalty. No License.



The "Toledo" Electric Welder Co.

CUMINSVILLE, CINCINNATI, OHIO, U.S.A.

Have you a Locker System in your Shop?

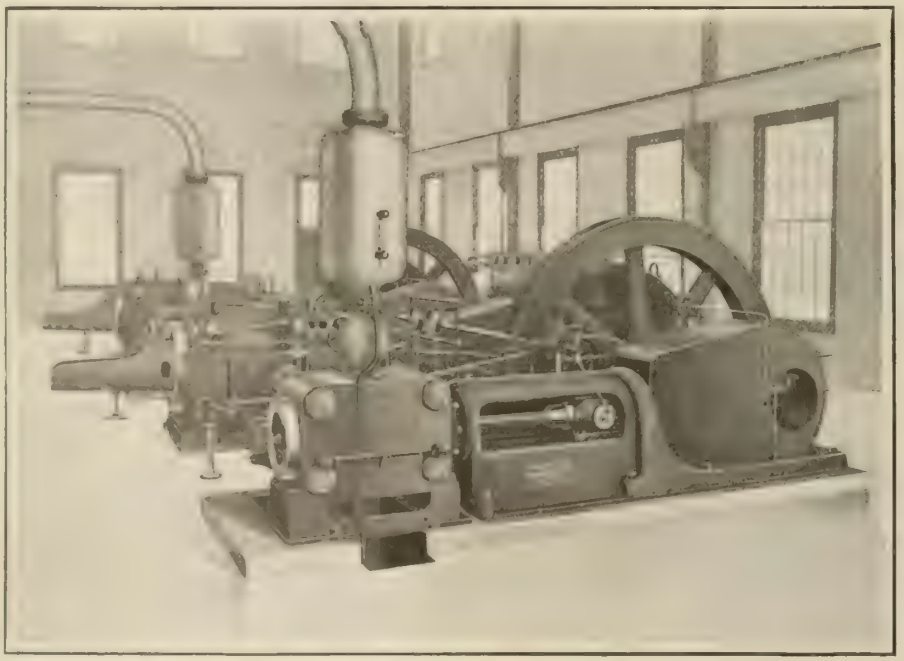
THE
SPLIT-BASE
IT'S NEW

THE WATEROUS SPLIT-BASE PUMP

The Waterous Horizontal Pump shown herewith is the type most extensively used for all purposes, and for general work is the best pump on the market. It is very strong and solid.

The pump has few parts to get out of order. It is put together to stay right and it does. The runner is of large diameter, of special wear proof material and runs comparatively slowly. The exceptionally heavy shaft is carried in a long bearing, lined with the best babbitt metal. The pulley is large, turned all over and perfectly balanced. The hub bearing is long, carries the runner without end play, and is furnished with a **split** bronze packing gland.

The split-base is its special feature, permits the removal of the operating parts without disturbing pump foundation.



The pump is built up in sizes up to 14 inch discharge opening. Pumps are always kept in stock and can be shipped immediately. For further information and general dimensions

TIN 60c. NOT YET BUT SOON IS PREDICTED

TRADE MARK

USERS OF "GENUINE" BABBITT

Are Confronted With a Serious Condition

WHY STAND FOR IT? MAGNOLIA METAL

Will sail rings around "Genuine" Babbitt at about half the cost per pound, and then save probably as much more in the reduction of frictional resistance, in longer wear, less fuel, less oil, less liability to squash or "shutdown" and less rebabbitting.

Engineers using Magnolia can spend their evenings at home and read the papers during the day.

Sounds Like Bragging, and It Is.

We have a right to brag, for we merely reflect the enthusiasm and high opinion of Engineers and great scientists and governments and others in all parts of the world, and we don't believe in hiding our light under a bushel.

Now is the time of times to test Magnolia on the bearings where you believe that only "Genuine" Babbitt will work.

It is an erroneous idea that Magnolia is a soft bearing metal. Magnolia will withstand 19% greater pressure than "Genuine," and as we have frequently pointed out, it is frictional heat that causes squashing, to which "Genuine" is very susceptible and Magnolia exceptionally immune, because possessing the lowest co-efficient of friction of any known metal with all of its co-related virtues and economies.

Please watch out for our ad., which will shortly appear, showing a remarkable test of Magnolia Metal by the United States Government, using WATER as a lubricant. It is an eye opener.

DON'T HESITATE, ORDER MAGNOLIA METAL NOW

Power Talk No. 3

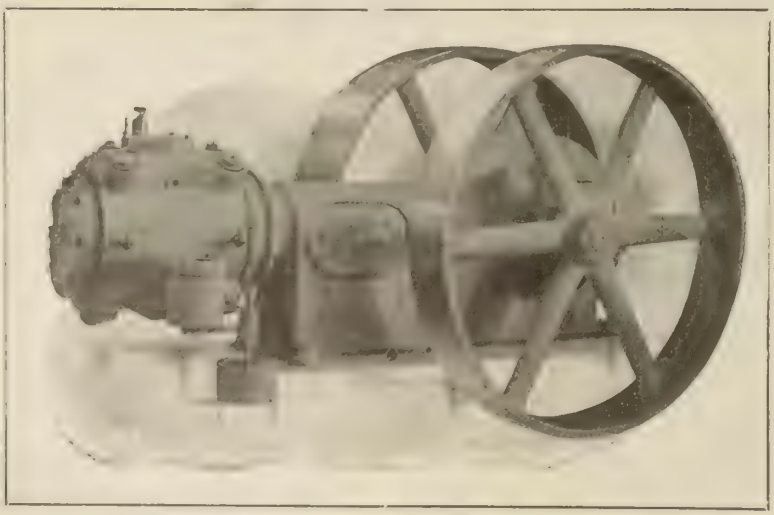
That New Power Plant

Will be installed with an eye to getting the best results from every ton of coal.

Your power transmission equipment should be bought with the same care.

The difference between the cost of power at your engine or motor and at your machine averages from 20% to 70%.

This is wasted in friction.



Chapman Double Ball Bearings are guaranteed to save 75% of this shaft friction and 95% of lubrication over any type of self oiling bearings.

They are now installed in over 1,000 Canadian factories. Send us a rough sketch of your shafting layout and we will advise you as to the amount of power that can be saved and the cost of installing Ball Bearings.

AIR COMPRESSORS

THE illustration is of a RAND Class "N E-I" Straight Line Belt-Driven Air Compressor.

This is an economical, automatic, high-speed, self-contained machine, which represents the very latest development in small power-driven air-compressors.

The excellence of design and construction of these small machines is unequalled. Every part is just as carefully manufactured as the largest type of Corliss Compressor, and the result is a machine of unusual quality.

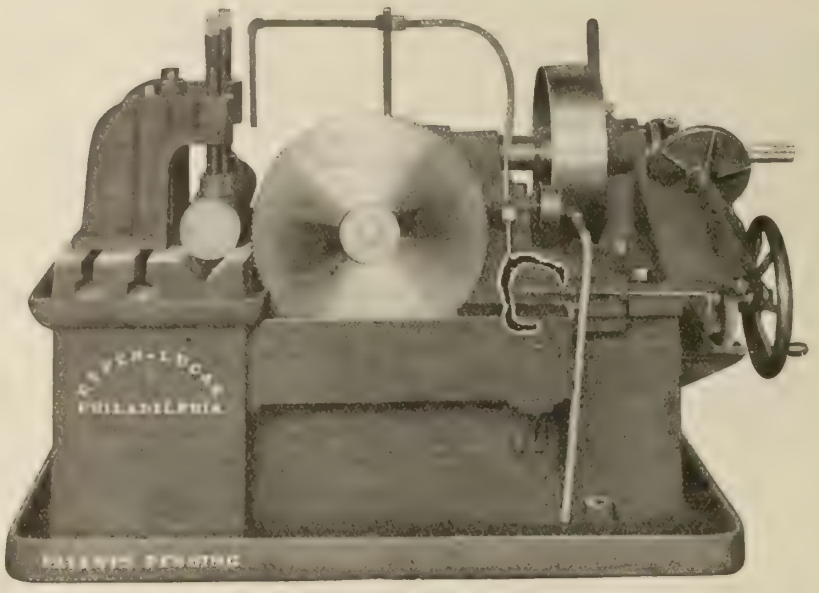
STEEL CASTINGS

By the TROPENAS CONVERTER PROCESS

We beg to announce that owing to the growth of our steel foundry business we are giving up the manufacture of grey iron castings, and in future by specializing hope to give still better satisfaction.



When new improvements at present under way are finished, we will have the most modern and best equipped steel foundry in Canada for the manufacture of steel castings up to 1,000 lbs. weight.

Cold Saw Cutting Off Machine

A Dividend Payer

THINK how many jobs you could do at REDUCED COST, with one of our cold saws. Many jobs are done on a Shaper, Slotter, Milling Machine or with a Hack Saw that could be done much more economically on one of these handy machines, leaving the other tools for the work they are particularly adapted for.

These Cold Saws can be fitted up with clamps for doing a great variety of work not only for general Machine Shops, but also Structural Shops; they will saw anything within the capacity of the saw.

They are of substantial construction, designed to withstand the severe strains developed when cutting through metal with a saw blade driven by powerful gearing.

Fig. 1 Finished Gun, Showing Mechanism.

Making a Double Barreled Shot Gun

By B. A. C.

The Shotgun is Such a Common Article That Few Stop to Consider How it is Manufactured. Gun-making has Become Such an Important Branch of Machine Shop Practice That There are in Use Many Special Machines to Facilitate Production, Not to Mention the Hundreds of Jigs for the More Expeditious and Rapid Handling of the Parts. The Only Shot-gun Factory in Canada, the Tobin Arms Mfg. Co., Woodstock, Ont., is a Thoroughly Up-to-date Example of What is Being Done in This Special Line of Activity, the Principals and Operators in the Factory Having Spent Years Developing Their Knowledge of This Special Line.

THE writer, when passing through the plant of the Tobin Arms Mfg. Co., Woodstock, was impressed with the multiplicity of operations necessary to produce even the seemingly most insignificant parts of a shot gun. To the casual observer, there is not much to a gun, but, if examined closely, it will be observed that quite a large number of parts enter into their make-up, necessitated largely by the more or less automatic action of the firearm, and also from the compact construction essential to a good gun.

This latter feature makes machining of the parts a considerable job, for from this compactness, every available space must be utilized, making many of the parts of unusual mechanical construction. Numerous distinct operations are required in most cases.

The frame of the gun shown at A, Fig. 3, affords a good example, for this part in itself requires 57 separate and distinct operations. Of course, this is the main part of the gun, and on it both figuratively and literally, the rest of the gun hinges. As with most of the other irregular parts, the frame is drop forged steel, and in the finishing, like nearly all the parts, the miller plays a very prominent part, being the principal machine employed.

A review of a few of the principal operations on the frame would be of interest in showing how a job like this would be produced. The first three operations are on the power miller, finishing up the two sides and back thereby squaring the piece for further operations. The next two operations are on what is called the "water table" at B and C. The two operations are necessary—too much for one cut. The first removes the flat face B, and the second, the perpendicular face C. Following this is a drilling and reaming operation on the joint pin hole D. The tang E receives the next attention being finished in the power miller under, above, and on the two sides in four successive operations. Next comes another power miller operation on the round joint end, which must of necessity be very accurate, of a true circular form. This is done by a formed miller, producing the work very rapidly. In order comes the lug cut F on the miller, which is the cut in the frame to hold the lug of the barrel. In succession follow the drilling, reaming, and slotting of the trip hole, finishing the recess G on each side in several operations by the hand miller, and the profiling of the lock cut, in the interior of the frame by the profiler. Between these various operations mentioned are many minor ones, principally drilling, slotting and broaching.

In all these varied operations, the point that stood out most prominently, was the expeditious manner in which they could be produced naturally. To make this possible, jigs, formed tools and milling cutters without number, are employed, many of them very intricate in form, but designed with the idea of simplicity of operation in view.

The fore end iron shown at H, Fig. 3, is another piece with a number of operations, 23 in all, of which the principal are the top face cut, two side cuts, wood cut, joint cut, all done on the the miller, and the drilling and broaching operations. The trigger plate, shown at A, Fig. 2, also has a number of different operations, the principal ones being on the hand miller. There are 19 in all. The upper cut shows the plate in its drop forged state, and the lower one, finished. B shows the frame and mechanism assembled, and C, the fore end iron in different stages of com-

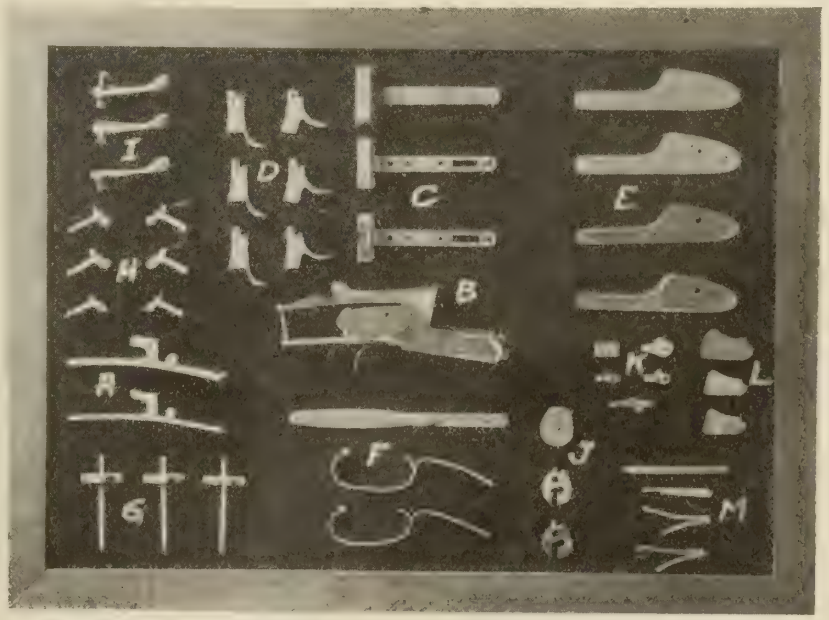

Fig. 2 Component Parts of a Shotgun in Various Stages of Manufacture.

pletion. The side view is given in Fig. 3. D shows the right and left trigger, in the different states of finish; E is the same for the lock plate, and F, the the trigger guard. For the latter it will be noticed that it is drop-forged in the flat state and then bent to shape. G shows the various stages of completion of the cartridge ejector; H, the right and left rear; I, the finished and unfinished top lever, (note the way it is drop-forged); J, the bolt; K, the cam lock and cocking cam in their various stages, and also assembled; L, the hammer; and M, the main spring, (note how it is produced).

Fig. 4 shows how the two barrels are united. Instead of being a solid, one piece forging, each barrel is finished to a certain point separately, and the two dovetailed together as shown, and brazed. This makes a very solid union, as the separting strain is not very great. After thus uniting, the final finish is given to the interior of the barrel in a special machine, where the finishing reamer shown in Fig. 5 is employed. It removes from .010 to .012 ins. in all, and must of necessity operate very slowly to prevent chatter, as the cutting edge presented is the whole interior length of the barrel. As shown the reamer consists of a square steel bar, three corners of which are dulled, and the fourth with a sharp edge, like a scraper. A shim of wood along one side (the proper side is indicated) makes the reamer fit the barrel snugly. Each operation removes but a very slight surface, and to change the size to remove more each time, very thin strips of tissue paper are introduced between the wood shim and cutting bar, increasing the size slightly. The cuts must be very small to obviate the before mentioned danger of chattering, as, once a chatter-groove is made, it is practically impossible to remove.

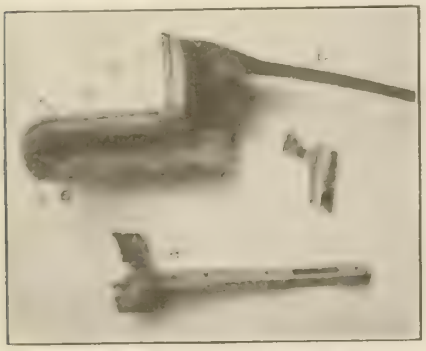

Fig. 3.—Frame and other Parts of the Gun.

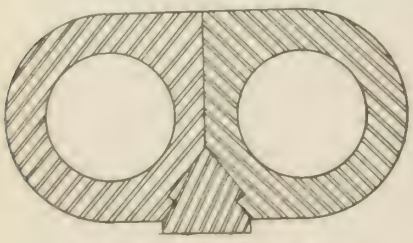

Fig. 4.—Cross section of Barrel.

Various other special machines and tools are employed reflecting credit on F. M. Tobin, vice-president of the company, and A. A. Lottery, superintendant, who installed the plant. It is due to these two men and particularly to the former, that there is at present a modern and efficient shot gun factory in Canada.

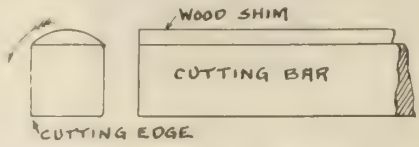

Fig. 5.—Finishing Reamer.

WIRE GAUGES SHOULD BE STANDARIZED.

A correspondent in "Scientific American" has called attention to the fact that there are some six or eight different gauges in use by the wire and sheet mills of the United States. There is often a difference of two sizes in the gauges, and a mistake in using the wrong gauge often results in a great deal of expense to one party or the other. If merely the size and not the gauge is given with an order, the mill must write back to ascertain the gauge, and much valuable time is lost. The writer suggests that either the manufacturers themselves should get together and decide on some one gauge, or the Government should take action in the matter.

NEW MACHINERY HALL.

An architect's drawing of the new machinery building for the Ottawa Exhibition Grounds, has been prepared. The building was designed by Mr. W. E. Noffke, architect. It will stand near where the old machinery hall is located, occupying the present roadway in front of that building. The lagoon in the exhibition grounds is to be filled up and only two small ponds with fountains in them will be left in front of the new building. The building will be 280 feet long and 140 feet wide. It is Japanese in architecture. The structure will have a steel frame and the outside will be of brick, built with Flemish bond. The trimmings and columns will be of concrete and the roof of red tile.

At the main entrance to the building will be Japanese towers, which will be illuminated with electric lights, forming two towers of light on either side of the doorway. There are also two Japanese towers on the roof also to be illuminated.

The columns in front and the gables will be treated in the best examples of early Japanese architecture. The floor will be of concrete and the inside walls treated in brick.

The canal runs at the rear of the building, which will be placed forward of the old bulding in order that the proposed route of the driveway may not be interrupted along the canal at this point.

BOLTS — SECTIONAL AREA UNIFOMITY.

By A. E. B.

Bolts that are subject to repeated shock and stress, those belonging to an engine connecting rod for example, give much more satisfactory service if the body is reduced in diameter to give an area corresponding to that of the bottom of the thread, or if a hole is drilled out to attain the same end.

With each shock there occurs a slight temporary elongation concentrated for the most part at the smallest diameter or area, i.e., the bottom of the thread between the nut and bolt body, Fig. 1.

The continuance of this condition leads to a crystallizing process being set up in the material, and ultimate fracture of the bolt, after it may be a brief service, irrespective of safe working calculation of sectional area.

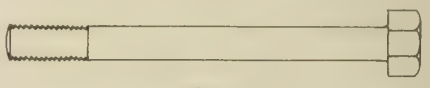

Fig. 1.

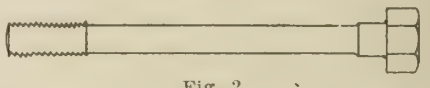

Fig. 2.

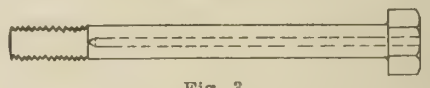

Fig. 3.

By reducing the area of the bolt body until it is equal to the area under the thread, the temporary elongation or stretching is distributed over a greater length and naturally the strain is less per particle of metal than otherwise.

Fig. 2 illustrates the bolt with the body diameter reduced, and Fig. 3 the bolt with the hole drilled into it. Both of these methods are in common use and each gives highly satisfactory results.

Preference is sometimes given to the method indicated by Fig. 3, for the reason that as it does not decrease the outer diameter, the twisting or torsional strength of the bolt is not impaired.

It is the practice in many cases to have this reduction of bolt area particularly referred to in specifications, and its more frequent adoption in general practice would be conducive to immunity from breakdown.

The McClary Manufacturing Co.'s "Welfare" Department

By Blackrock

A Growing Tendency is Being Manifested Among Large Employers of Labor in the Direction of Improved Social Conditions for Their Employees. The Movement is One Which Naturally Meets With the Approval and Hearty Co-operation of the Latter, and While Only Just in its Infancy and Experimental Stage, Gives Promise of Far-reaching Results in Producing Amicable Relations Between Capital and Labor.

THE McClary "welfare" department was organized about a year ago on the initiative of the company, which step ranks them among the pioneers in the opening up of this field of factory social extension and development. "Welfare" as applied to employes is interpreted to mean "anything done by an employer for the benefit of his employes, which he is not compelled by law or expected by custom to do."

Features of the Work.

At the foundry plant in the east end of the city (London, Ont.) is to be found a perfectly equipped emergency hospital, and at their wares plant in the centre of the city is to be found a similarly equipped institution.

A graduate nurse is employed by the department and devotes her whole time to the cause. She gives advice as to the sanitary conditions existing throughout the plants, gives first aid assistance in case of accidents, dresses the wounds of such persons until completely recovered, and visits employes at their homes in sickness.

During the year just closed the nurse (Mrs. Reynolds), attended 26 accidents, made 619 dressings, and paid 240 sickness visits. In addition to the nurse, attendance and service, a doctor visits the factories daily at the noon hour.

Lunch Room, Library, etc.

At each plant there is a cafe under the care of an experienced chef. Here wholesome food is supplied at cost to all who care to avail themselves of it. A daily average of 360 lunches are served, and separate lunch and rest rooms are provided for girls.

In winter, games, entertainments and lectures are provided at the noon hour, while in summer outdoor recreation in the form of tennis and baseball are the features.

McCLARY'S

WELFARE DEPARTMENT

Each plant is equipped with a library, supplemented by loans of books from the public library of the city. A fee of one cent per week is charged for the loan of a book, which fee is put into a new book purchase fund.

Fig. 1 is a view of the emergency hospital; Fig. 2 that of the library, each being intensely realistic of its particular purpose. The library boasts 633 volumes on its bookshelf.

Report of the Work.

The annual general meeting of the welfare department was held on Monday evening, 6th February, at which gratifying reports of the previous year's work were presented, and office bearers for the ensuing year appointed.

Col. W. M. Gartshore, vice-president of the company, and J. K. H. Pope, secretary, are chairman and vice-chairman of the welfare executive respectively, the other members being drawn from the various departments.

A striking phase of the work is the enthusiasm displayed by Col. Gartshore and pride taken by him in what has been already achieved, as evidenced in his availing himself of the daily lunch when opportunity offers.

A Progressive Ideal.

Effort of this nature is progressive if successful, in that one feature leads to another; this being so, additional ground is sure to be broken during this second year of institution. Too much has not been attempted to begin with, just sufficient as it were to prove it to have been worth while.

Work such as we have described is not in any sense charitable, its essence is not the giving of something for nothing; it is rather an educative, elevating and humanitarian purpose, having in view the cultivation of a spirit of help-

Fig. 1—Emergency Hospital, McClary Mfg. Co., London.

Fig. 2—Library, McClary Mfg. Co., London.

ful, thrifty and honest man and womanhood.

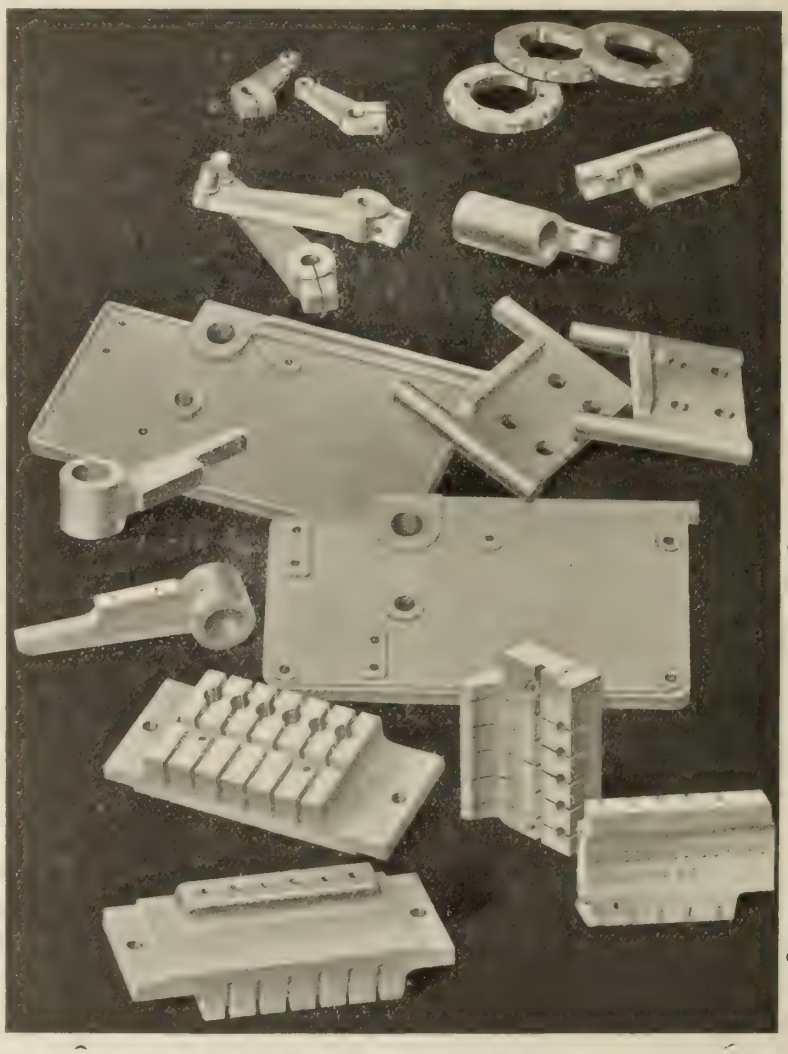
We look for the example of the McClary "welfare" department being imitated in other manufacturing centres of the Dominion, and it is not too much to expect that as the scheme develops, there may at least be provincial executive boards who will meet to discuss and further this co-operative movement of capital and labor.

The McClary Booster Club.

The McClary booster club is really an offspring of the welfare scheme, and exists to provide healthful amusement and entertainment on stated occasions to the employes and public. The meetings are held in the company's large dining hall, and consist of smoking concerts, illustrated lectures, dance and euchre parties.

George Moll, chief engineer of the wares plant, is president, and as in the case of Col. Gartshore and the "welfare" scheme, not a little of the booster club's success is due to him. The admission to the meetings is restricted to 10 cents, an amount entirely disproportionate to the quality of entertainment usually given.

"The Free Press," London daily, has donated a trophy to be awarded the society which has done or is doing most for the city's welfare. The booster club is entered, and high hopes are entertained that "McClary's" will be the judges' selection.



This article has featured at some length an excellent work that is being done by the co-operation of employer and employe, and we hope to continue the series by describing from time to time other concerns engaged in a like worthy compact.

DIE CASTING.

ONE of the most successful of the modern methods of manufacture and one which has created considerable interest of late, is that commonly known as diecasting. The Franklin process was originated about eighteen years ago by the H. H. Franklin Mfg. Co., Syracuse, N.Y. In the Franklin process steel dies are used in the place of sand moulds and into these dies the molten metal is forced under pressure, by means of especially designed machines. This results in smoothly finished castings accurate to the thousandths of an inch and with holes, slots, lugs, large threads and engraving accurately located. In fact the accuracy obtained by this method of manufacture is in many cases greater than can be secured by machining. Tin, zinc and lead based alloys are most commonly used, the normal strength being about that of cast iron, but the castings may be further strengthened by the inserting of brass or steel stampings, pins, etc., in the process of casting, wherever special toughness is required. In general, die castings range from 1-16 of an ounce to 4 lbs. in weight.

The extent to which the process has gained favor can be seen by the fact that 64,000 Franklin die castings were used in the construction of the 1910 census tabulating machines, used by the U.S. Government. The automobile industry has also found die castings of great advantage; engine bearings, oil and water pump, timer and magneto parts are produced chiefly by this process. Small gears, type wheels, telephone, electric and vending machine parts lend themselves readily to die casting. Many parts which if produced by the usual machine methods would have to be made up in sections and assembled may be die cast as a unit. In such cases the saving is especially noticeable.

The steel dies used in the construction of die casting must of necessity be very accurate in order to secure the desired results, and none but the most skillful workmen can be employed in their manufacture. As a result of the die cost, die castings are at present better known in the United States where the quantity of duplicate parts used is much greater, but many of the Canadian manufacturers are beginning to realize the benefit resulting from their use in even moderate quantities.

Parts Cast by the Franklin Process and used by the U. S. Government in the Construction of the 1910 Census Tabulating Machines.

SHEELITE.

Sheelite, one of the minerals containing tungsten, has been discovered in Halifax County, Nova Scotia. It is of no known use in itself, excepting as an ore from which tungsten may be extracted. The mineral is chemically a tungstate of calcium. As an ingredient in the chemical side of steel making, it is quite important. At present the world's annual output, coming mostly from Sweden, is placed at 4,000 tons. If present indications are correct, the recent discovery in Nova Scotia will not only yield sufficient for the steel plant in the province, but will have an effect on the markets of the world. The ore is reported to yield 60 per cent. of tungsten acid to the ton of sheelite. At present 25 men are at work on the preliminary experiments. Hiram Donkin, deputy commissioner of mines, Halifax, Nova Scotia, will, give interested parties all reasonable information.

Pneumatic Appliances at the G. T. R. Car Shops, London, Ont.

By Halyard

The Opportunity for the Introduction and Development of Methods and Devices Toward Quicker, Less Laborious and More Economical Output, Exists to a Lesser or Greater Extent in Every Manufacturing and Repair Plant. We are Not Assuming Too Much in Stating that Possibly Those Plants Devoted Entirely to Repairs and Renewals Give Wider and More Effective Scope to Inventive Genius Than do Others of New Production Only, in That "Stern Necessity, the Mother of Invention," Demands the Exercise of the Highest Ingenuity and is Unsatisfied With Less.

THE sketches and description of the appliances which form the subject of this brief article were gathered in the course of a few hours' sojourn in the G. T. R. car shops, London, Ont., and while perhaps in no sense displaying hitherto unknown features, and being peculiarly adaptable to the special character and necessities of the work there, the great bulk of our readers will we are sure be interested, and modified arrangements of some or all of the appliances described, will possibly find adaptation by them in new fields.

It is to be borne in mind that these various appliances are in no sense standard, nor is it intended they be adhered to strictly in arrangement of detail by those interested to the extent of adopting them. The aim is rather to show in a general way a few of the uses made, as ideas developed in a particular shop piped with compressed air for other and what might be termed more important and primary purposes. That being so, modifications, improvements and entire change of design will in all probability suggest themselves to many, and new appliances arise from the cue given.

As hinted in the preamble, repair and renewal shops are prolific of inventive genius. Break-downs and smash-ups necessitate most always rush putting-to-rights again, to attain which requires keen discernment of the right and best thing to do and the most helpful and often improvised equipment to do it.

Many methods and devices employed on such occasions are carelessly and thoughtlessly lost track of daily, and the profession is the poorer for it. An insufficient realization of their intrinsic worth by those giving them conception and an all-absorbing desire on the part of the administration to get things going again, combine to bring about the want of record referred to.

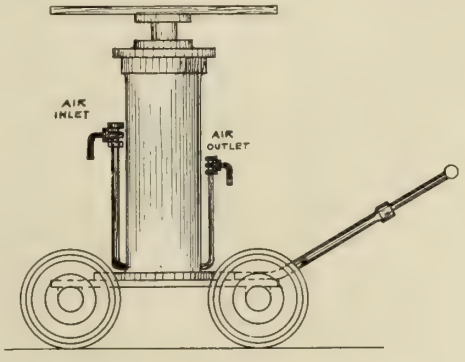


Fig. 1—Draught Timber Placer Jack.

We would like to digress a moment here and say that methods used by a mechanic to produce a piece of work of super quality, most economically, when made a regular practice of, are devices worthy of a place in the columns of this journal, and while lightly thought of and considered unimportant by the user, from a publicity standpoint, show themselves otherwise in the persistency with which they are adhered to and applied in practice. This is a point worthy the serious consideration of all engaged in the mechanical arts. Further, publicity given your methods and devices while admittedly helping the other fellow along, ultimately helps you, as he too has something to give.

The result of this distribution of ideas spells progress, progress leads to perfection, comfort and comparative affluence of the vast majority, and your duty lies that way.

Portable Draught Timber Placer Jack.

Fig. 1 represents the portable draught timber placer jack, and as its qualification implies, is used for running in underneath the cars, pushing the draft timber into place and holding it there until it is bolted up. The air cylinder is 5 inches diameter, the trolley wheels 8 inch diameter, 15 inch centres and the extreme width of truck 20 inches. The cylinder may be either a casting with upper head bolted or screwed on, or a piece of heavy wrought iron pipe bored out, with both heads screwed on. The lower head is bolted to a steel plate base which in turn is attached to the trolley wheel axles. On top of the piston rod a steel plate, 8 inches by 18 inches, is attached for the purpose of carrying the draught timber.

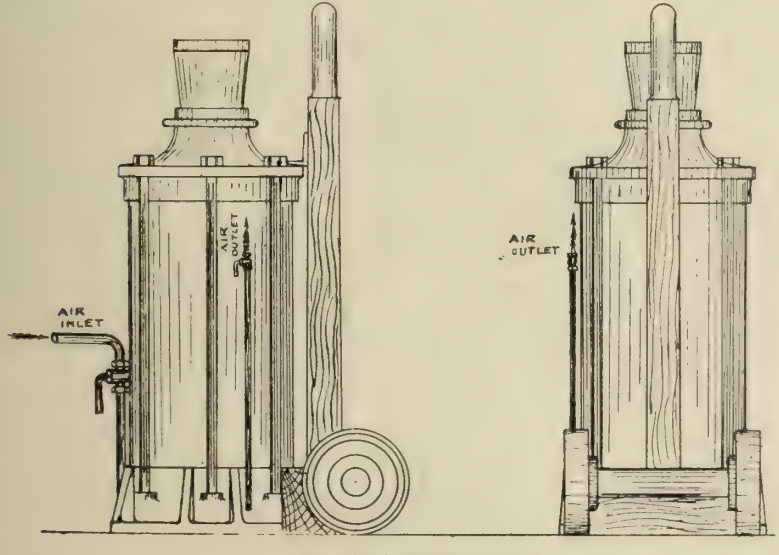

Fig. 2—Car-lifting Jack.

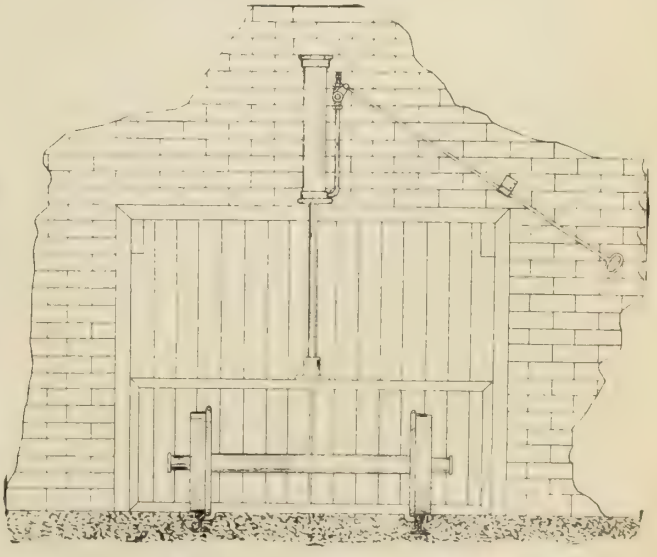

Fig. 3—Door Section Lifting Apparatus.

Car Lifting Jack.

Fig. 2 is representative of the car-lifting jack, and is necessarily heavier and more powerful than the other. The

cylinder diameter is 10 inches, and its purpose the bearing of a part in lifting empty freight cars off the trucks. Its base rests on the ground when in action, and for convenience in moving it around one pair of wheels and a heavy shaft complete the transportation facilities.

Door Section Lifting Apparatus.

Fig. 3 is an arrangement peculiarly

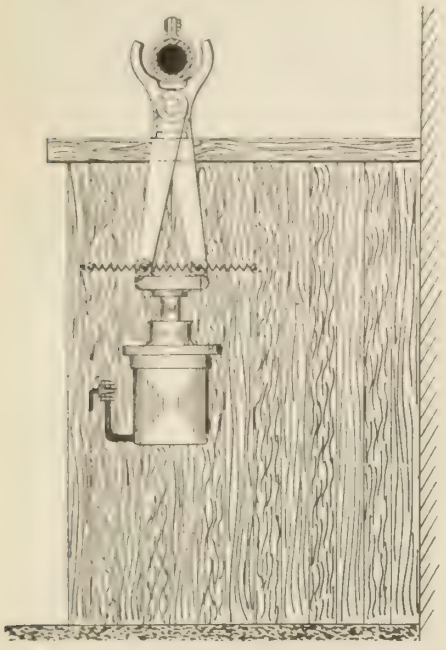

Fig. 5 -Air Brake Hose Clasping Device.

adaptable to railroad and street car shops. The door section lifting apparatus permits of the complete wheels and axles, trucks for that matter of it, being let out or taken into the shop without the necessity of opening the whole large door in cold and stormy weather, a proceeding which is more or less clumsy and slow.

The cylinder diameter in this case is made large enough together with the pressure to carry up the door section required, and the piston stroke long enough to suit the height of lift.

The operating lever to the right of the sketch enables the attendant to manipulate the aparatus with the greatest of ease. The lever actuates a 3-way cock allowing air admission to lift the piston, air shut-off to hold it and the door in position, as long as necessary, and air release to allow the door to close again. The cylinder details in this, as in the others described, may be all castings or part wrought iron pipe and part castings.

Air Brake Hose-Nipple and Coupler Inserter.

Fig. 4, the air brake hose nipple and coupler inserter, consists of a vertical acting air cylinder which clamps the standard length of hose, and the horizontal air cylinder with the nipple on its piston rod, which pushes the nipple into place, thereafter sliding the vertical cylinder and clamp endways toward the die block in which is laid the coupler. The horizontal movement pushes the hose onto the coupler.

The cylinders are in each case about 6 inches diameter, the vertical cylinder and standard being attached to the lower half clamp which in turn slides on four slot hole guide studs inserted in plate attached to an ordinary vice bench. Air admission and release is applicable to both ends of each cylinder.

Air Brake Hose Clasp.

Fig. 5 represents the air brake hose clasp attached to the end of the bench and adjacent to the nipple and coupling inserter. It consists of the air cylinder, piston and piston rod, the latter with a cap to opposite sides of which each half of the lower end of the squeezers is attached to permit of oscillation. From these centres light spiral springs are carried to and on opposite sides of their respective squeezer arms. These springs admit of the jaw grip being released when the air is released, and prevent a clasped downward pull when the piston descends.

The sketch otherwise is self explanatory and need not be dwelt upon. The advantage of the apparatus is that the clasp or band flanges are closed up, admitting of the bolt being inserted and the nut tightened up by hand. A spanner to tighten the nut is unnecessary, because although only applied by hand, the slight reactionary spring due to the withdrawal of the jaw grip locks the nut tight.

The saving of labor in the equipment of air brake hose by the sketch arrangements, Fig. 4 and 5, is 100 per cent. gain in economical production, and we should say were it possible to compute, an equivalent gain and comfort of operator.

Employes' Welfare.

In a near future issue of Canadian Machinery we hope to describe the arrangements made for the welfare of the employes in the G. T. R. car shops, London, Ont., believing also that these will be found of much interest to all our readers.

Much of the development and adaptation of suitable labor saving equipment as also the initiation and successful outcome of the employes' industrial and social welfare scheme is due to efforts of Mr. Thos. A. Treleaven, master car builder, to whom we are indebted for the opportunity of acquiring the foregoing information.

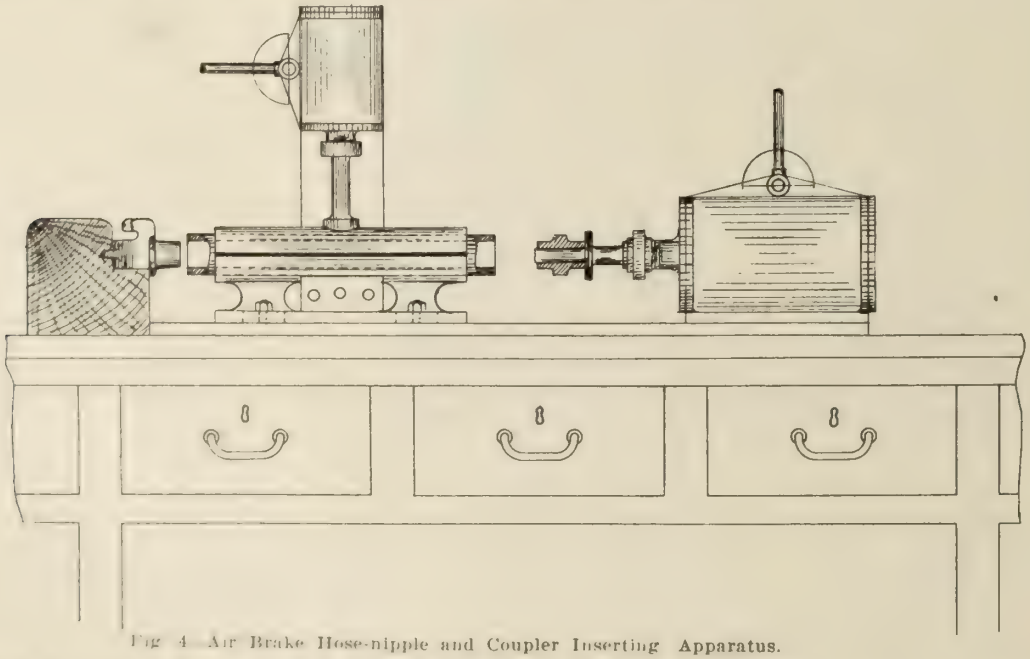

Fig. 4. Air Brake Hose-nipple and Coupler Inserting Apparatus.

Twist Drill and Other Internal Cutting Tool Practice

Modern Shop Practice has Developed Various Types of Twist Drills, Reamers, Counterbores, etc., Greatly Increasing the Capacity of the Machines Using These Small Tools. The Breakage of Tangs Formerly Caused a Great Loss, But This has Now Been Eliminated by Modern Methods.

ONE of the most common small tools in the machine shop is the twist drill, and it is probably the most abused. When a young fellow begins work in a machine shop, either as an apprentice or as a machine hand, the first work is usually drilling. He is led over to the drill, given a jig and a drill and told to "drill these."

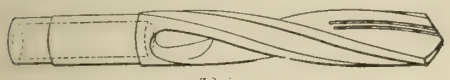

Fig. 1—Hollow Drill.

What the young chap does not know about drilling and shop methods would fill volumes. In the ordinary Canadian shop there is no central tool room, and the young chap is strictly "up against it." It is at this stage that the young fellow learns many things about drilling that he must "unlearn" later.

When the writer entered the machine shop he was given the job of milling tie pins for three months. For this he received fifty cents per day. About that time there was a call for volunteers for the Halifax garrison and it made a number of vacancies in our own shop. The writer was given the task of drilling malleable guards at seven cents per hundred, and malleable rings at twenty and twenty-five cents, and it was understood that he could make $1 to $1.25 per day. At the same time another apprentice was given the job of drilling pins. He had an old drill situated near mine with a big lever and a sliding table instead of the spindle and sleeve type, but made a dollar a day drilling pins at from five to ten cents per hundred.

We were located away from the rest of the shop and with the exception of rough emerys for grinding the burrs off the gray iron and malleable castings, there were no tool grinders within three or four hundred feet. It meant a big

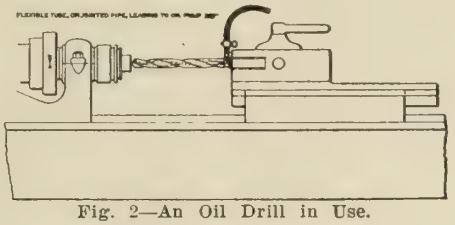

Fig. 2—An Oil Drill in Use.

loss to us to go down there every time we wanted to sharpen a 9-64, a 3-16 or a 7-32 inch drill as the case might be. We solved the difficulty by filing off the side of an emery wheel close to the centre and succeeded in making a good job out of one that had formerly been looked upon as one of the worst in the shop.

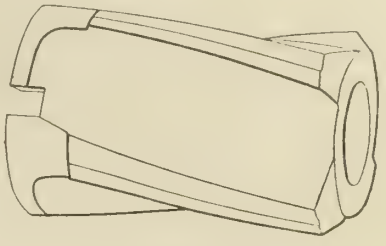

Fig. 3—Shell Drill.

Since that time the writer has been interested in the progress of drilling. Some data which would have been valuable in the old shop days, has been collected and some extracts from the pages of the diary are here given.

Some Types of Drills.

The twist drill of standard form is made with two lips and two grooves, which either make a constant angle with the axis or one which increases gradually from the point upwards. The increased twist is given in order to counteract the thickening of the web from point to shank, imparted to resist the

Fig. 10 Table of Drill Feeds.

tortional stress to which the drill is subjected.

A centre drill is a short twist drill used for centring shafts before facing and turning. Sometimes a combined drill with a 60 degree taper is used to drill the shaft and countersink it at the same time, thus avoiding two operations.

Hollow Drills.

Fig. 1 shows a hollow drill used for drilling long holes such as lathe and

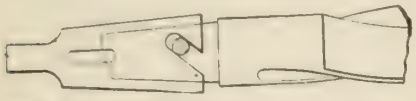

Fig. 11—Driving Broken Tang Drill.

drill spindles. The shank can be threaded and fitted to a metal tube of a length to suit the work.

Fig. 2 is another type used when the work revolves and the drill remains stationary. The oil cup is connected to the oil pump, forcing out the chips and keeping the point cool by a steady stream.

A shell drill is shown in Fig. 3. It is used for reaming out holes after a standard drill or cored holes. The arbor is the same for several sizes, so that the cost of shell drills is comparatively small.

A similar method is used so as to obtain the benefits of high speed steel at low cost. Drill tips are made with a small shank of about ¾ inch which is

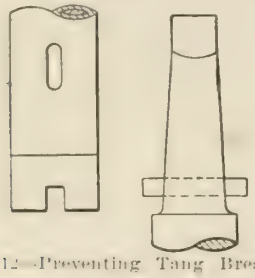

Fig. 12—Preventing Tang Breakage.

threaded. This size is adopted as standard for the shop and any size drill fits one shank which is tapped to suit. The same practice is followed for reamers.

Sharpening Drills.

With a drill the hole may be cut "oblong" if or much larger than the drill. A user of drills should therefore be familiar with the manner of grinding a drill to cut the right size with as little power as possible. To cut right the right size the lips must be exactly the same length and the same angle. Fig. 4 is a gauge which gives the lip edge angle of 59 degrees and at the same time assists in getting the true centre.

Fig. 5 is a gauge which shows how to get both lips alike, but does not give the angle.

In Fig. 6 the drill has been relieved back of the cutting edge, making it similar to a flat drill. As the drill wears down, it is often necessary to thin the point as shown in Fig. 8. This results in doing quicker and better work.

The angle of the point forms an angle of 135 degrees with the cutting edge as shown in Fig. 9. The best clearance for drills is from 12 to 15 degrees depending on the hardness of the metals, the greater clearance being used on the softer metals.

Drill Speeds.

In addition to a knowledge of grinding, the user should learn to run drills at proper speed. He will then require to grind seldom and will have few breakages. For steel use a speed of 30 ft. per min.; for cast iron, 35 ft. and for brass, 60 ft. per min. For drilling steel with a 1-16 inch drill, this means 1834 r.p.m., while for brass it would mean 3668 r.p.m.

The table, Fig. 10, taken from the American Machinists' Handbook, gives the speeds for all drills up to 3 ins. These speeds require plenty of lubricant and are for carbon steel drills. High speed steel drills will stand about double these speeds.

Drill Shanks.

One of the great wastes in drilling practice is in the breaking of the drill tangs. This breakage is caused usually by a lack of grinding and drill speed knowledge. Manufacturers of drills have placed on the market drills with straight shanks, double grooved shanks, sockets using pins, double tang sockets, etc. All these have been of value. By means of such schemes as the double tang sockets, drills have been reclaimed from the scrap heap.

Fig. 11 shows a method of driving a drill with a broken tang. The writer has drilled holes through socket and drill shank and inserted a pin. Fig. 12 shows a scheme for overcoming the breakage of tangs altogether.

All High Speed Steel Drills.

Fig. 13 shows a vanadium high power twisted drill. The steel used contains a very high percentage of tungsten with the adition of vanadium and chromium. The special feature is the "increased" twist. The illustration also shows the socket. At the mouth of the interior of the socket there is a circular steel boss or pin, which fits into the spiral grooves of the twisted shank and engages in direct contact with the drill. This pin relieve the tang from pressure of driving.

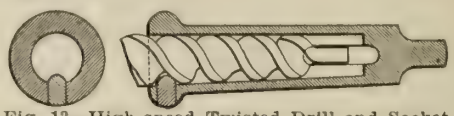

Fig. 13—High-speed Twisted Drill and Socket.

Fig. 14 shows a high speed steel drill made from flat bar stock. Pieces are riveted to the flat shank to give it the conical taper of the usual cut twist drill.

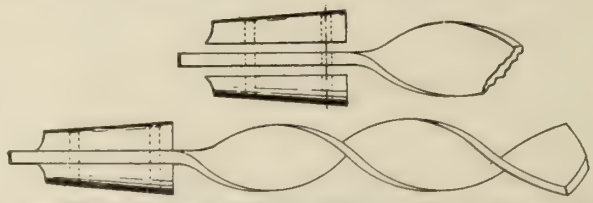

Fig. 14—"Flat" Twisted Drill is Made Ready for Taper Socket.

INSTRUCTION IN SHOPS.

Dr. Galbraith, dean of the School of Practical Science, Toronto, writing in his report refers to instruction in shops. He says that in addition to advancing means of transportation the University may soon be called upon to increase its facilities for coming into closer touch with trades and manufacturers. Industrial education is now a live topic. There seems to be no great reason why scientific and trade schools should not be established in their own works by the proprietors. A sufficient number of qualified teachers may be found among the officers and foremen to make a beginning. By proper co-operation between employers and their operatives such schools should be a success and justify their cost.

The University should provide for the education of the heads of the scientific departments in such works, and incidentally it may be of service in advising and encouraging the teachers in the works school. This method of initiating industrial schools would reduce to a minimum the danger of establishing them where they may not be needed. It will soon be necessary, he states, to help the shipbuilding industries by instituting a course in naval architecture.

In cold weather, steam generated in electric boilers will be used to maintain the temperature in the cars, and keep the various connections from freezing, when the trains of the Pennsylvania railway, entering New York station through the electrified tunnel zone, are disconnected from their steam locomotives. These electric boilers will utilize the 600 volt direct current from the third rail, and generate steam at 80 pounds pressure.

Machine Tool Manufacture---Quality and Guarantee

By Penstock

Being a Brief Review of Difficulties and Grievances That Arise Between Builders and Users of Machine Tools, Showing in Most Cases That the Lack of a Proper and Courtly Exchange of Opinion and Action Upon Opportune Advice May Lead to Unwarrantable Conclusions Being Drawn by Both Parties Concerning the Transaction of Sale and Purchase Between Them.

THE design, equipment, test and guarantee put up to-day by makers of machine tools may be generally reckoned as of a very high-grade, so much so we think as to be beyond question to the limit of human specialization, foresight and insight presently existing.

The purchaser, however, does not always see it in that light, and trouble between the manufacturer and user results. Inaccuracy of work produced by the machine is the fruitful cause, and an often unreasonable deduction on the user's part hastily arrived at, gives the maker credit for careless construction. A condition like this is naturally unsatisfactory and annoying to both parties, reflecting as it does on the manufacturer and his business, and injuring it may be, the quality and quantity of the user's output.

In the writer's experience probably the chief element affecting the reliability of a machine is that due to the user taking it to pieces for examination purposes, when it arrives from the builder. That he is perfectly within his right in doing so no one will gainsay, but that he shows wisdom in his action is open to serious doubt.

I have often wondered if curiosity to see the very vitals of his purchase is not in some real sense suggestive again of the eagerness of childhood to break the outer shell of its toy to investigate the source of the "squeak," and if the result in either case has not a parallel in that neither are qualified to replace properly the whole again.

The practice, mark you, is followed by expert users and may not always be chargeable to quest for opportunity of criticism ; but to a desire and the very laudable one of admiring the constructive design and workmanship.

From whatever motive the dismantling takes place, a grave error is committed. The user seldom has the equipment to re-assemble the machine as it should be and was, when it left the manufacturers' hands. The latter is the real architect of its structure, the former simply buys the use of it.

A man when he buys a home does not take it to pieces, and being satisfied try and put it together again with a view to living comfortably. He rather relies upon and accepts his own judgment in the purchase believing that he has got what he bargained for from a reputable seller.

Machine tool builders cannot afford to-day to be other than reputable, it is their particular and chosen business, they are equipped for it and are willing to guarantee their individual output. As a user then give them that trust you like reposed in yourself, by refraining from dismantling their product and piling cost and worry on yourself and them.

Most machine tool makers record the tests of their product, and furnish the purchaser with a copy showing the limit of error established.

As distinct from the source of trouble just discussed, other features of heart-burning are quite common. One of those is inaccuracy of levelling when the machine is installed and the want of verification after operation has been going on for a few months. This inaccurracy of level is due in large part to the want of proper appliances or to improper application of them.

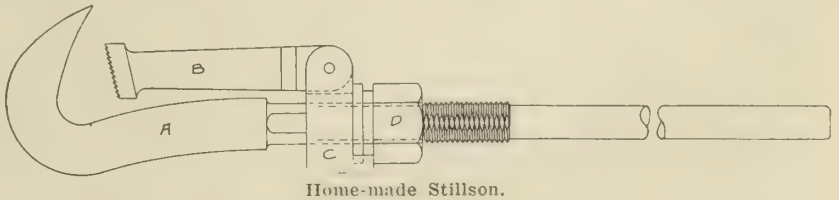
Levelling should be done lengthways and across, before the machine is bolted to its foundation. Wood packing or wedges to which oil or water may have access and settlement of foundations are each conditions liable to affect originally correct setting and require careful keeping track of.

Some makers make a point of informing their user purchasers of what to do and what not to do, a course made necessary for their protection and emanating from past experience.

A lathe manufacturing concern we have in mind impresses on its customers the necessity of carefully trying out the tool and asks to be thereafter informed as to faults or otherwise. They especially lay stress on the unwise course of attempted rectification by the user, and urge their willingness to replace defective parts or provide expert adjustment where necessary. The manufacturer, as we take it, is prepared to furnish the machine complete and perfect for the work, leaving the operator to see to his own particular sphere.

Another feature that users do not sufficiently realize, although laid great stress upon by the manufacturer, is the question of sufficient lubrication. Machinery in motion of any description, depends for its continuous and efficient running with minimum tear and wear, on regular and systematic lubrication.

For machine tools best quality mineral oil is recommended, having in view the high speed and heavy cutting demanded in present day practice. Like quick revolution, forced and self lubricating engines, the wear on bearing surfaces of machine tools should be nil. The lubricant should be of quality and quantity to form a film between the surfaces, which film in its turn prevents contact of them, and by cutting out wear enables the machine to maintain a continuous accuracy of production.



From what has been said it will be realized that much is to be gained by maker and user alike from a proper understanding of the question as it relates to each. The tendency we are glad to say is in all business relationships, to deliver to the hilt and to consummate a square deal.

Every known existing obstacle should therefore be thrown aside, not only as between machine tool builder and user, but with respect to every other business relationship of man and man.

HOME-MADE STILLSON.

The usual Stillson wrench, costly as it is, is often dispensed with in places where it would prove quite useful, other tools taking its place. Wm. Kennedy & Sons, Owen Sound, have a home-made article, which while costing but a fraction of the real article, meets all their shop requirements.

The body of the wrench, A, consists of a forging bent, as shown at the left with the right-hand end turned down to form a handle, the upper part of the handle being threaded, and the sides milled flat to the thickness of the handle. The gripping jaw, B, is a steel forging, with teeth, as shown, the whole being pivoted on the sliding part, C. The sliding part, C, is shaped to fit loosely over top of the threads, and the flattened sides, the latter preventing its turning. The lower face of C has a lip, which engages in an annular groove in the nut, D, which may be revolved to give the proper adjustment. All the parts being forged are very strong. Several different sizes are in use.

Home-made Stillson.

Boiler Design, Construction, Operation, Repairing and Inspection*

By H. S. Jeffery

The Various Points in Connection With Boiler Practice Will be Clearly Taken up in This Series. The First Article Deals With the Boiler Shell, Including Repairing, Factor of Safety, Hydrostatic Test and Number of Courses. The Series Will be a Complete Text Book on the Subject of Boilers, and They Should be Preserved for Reference.

Size and Number of Boilers.

(8) In deciding upon the length and diameter of a tubular boiler, the boiler designer is called upon to consider many matters. The steam pressure per square inch is one consideration, and the boiler horse-power desired another consideration. Decide these; then size and number of boilers.

The solution of whether one large boiler, or two or more smaller boilers should be installed, must be governed by the circumstance of each case.

The purchaser will be inclined as a rule towards the large boiler rather than two smaller boilers on account of the former in regards to first costs being cheaper than the latter.

The boiler room having only one boiler usually means Sunday work for the operating engineer; the passing over until a "more favorable time" repairs which should be made promptly and which if made at the right time would in many instances have saved the owner considerable, and in other cases would have prevented a boiler disaster.

With a battery of boilers it is not difficult to cut out of service one boiler for repairs without causing a shut-down of the plant or part thereof—in fact it is the practice with some when installing a battery of boilers to install one or two more boilers than necessary, the same being out of service, except when used in lieu of one of the regular boilers.

It is advisable and true economy as a general rule not to depend upon one boiler. There are instances where plants at their busiest season, employing considerable force, have had to shut down for several days in order to make repairs to the boiler.

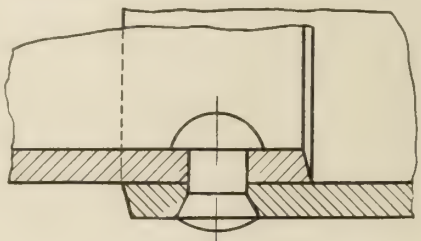


Fig. 9.

The length and the diameter of a boiler is sometimes a mere matter of choice. Other times the designer must consider the space allotted for the boiler. Perhaps it is the desire to install a 66 inch by 16 feet boiler, but the limited space will require the length to be limited to 14 feet. In this case it would necessitate increasing the diameter, or in lieu of the 66 inch by 16 feet boiler there would ordinarily be installed a 72 inch by 14 feet boiler.

Shell Thickness Increases with Diameter

(9) Increasing the diameter of a boiler means an increase in the force acting upon the longitudinal plane. For instance: The force acting on the longitudinal plane of a 66 inch by 16 ft. boiler will be with 100 pounds pressure per square inch as follows:

66 x 192 x 100=1,267,200 pounds.

With a 72 in. by 16 ft. boiler, same pressure per square inch as in the foregoing example, the total load on the longitudinal plane will be:

72 x 192 x 100=1,382,400 pounds.

Thus, 1,382,400—1,267,200=115,200 pounds difference.

In considering the diameter of the boiler and the thickness of the shell plate, it is necessary to consider the efficiency of the longitudinal seam. For instance: The allowable working pressure on a 66 inch by 16 ft. boiler, plate 60,000 tensile strength and 7-16 in. in thickness, factor of safety of 5, efficiency of longitudinal seam 70 per cent., will be:

$$\frac{60{,}000 \times .70 \times .875}{66 \times 5} = 114 \text{ pounds.}$$

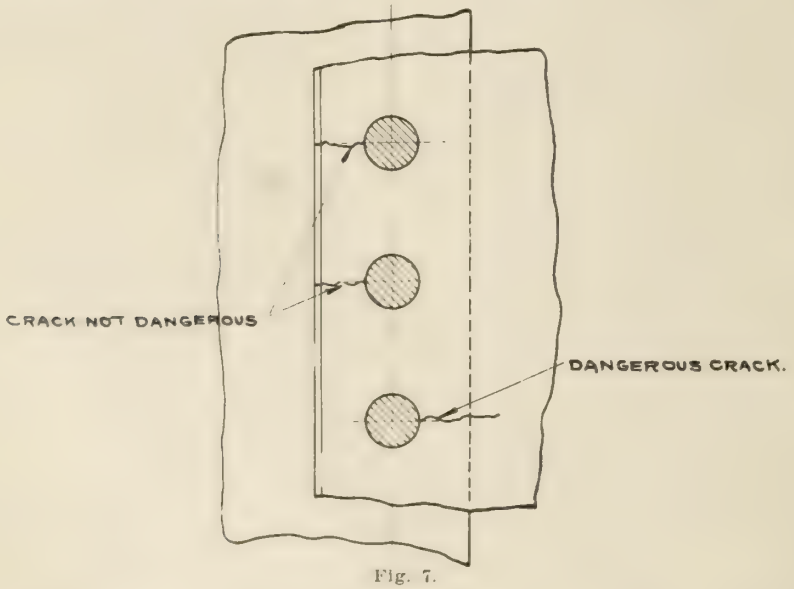

Fig. 7.

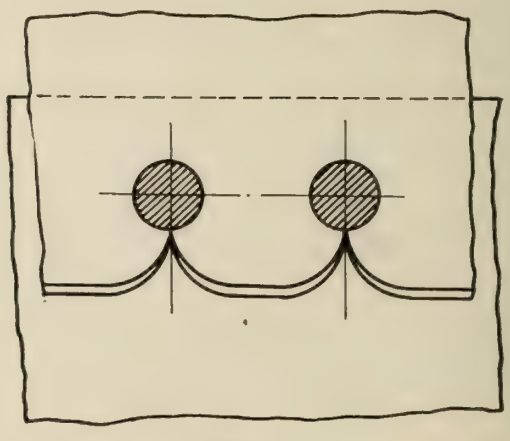

Fig. 8.

Now, a 72 in. by 16 ft. boiler, same as the above in regards to tensile strength, thickness of plate, factor of safety, but with a longitudinal seam having an efficiency of 80 per cent., will be allowed:

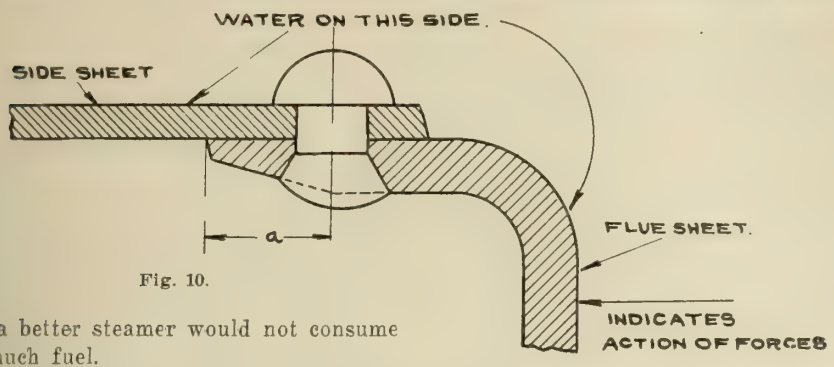
$$\frac{60{,}000 \times .80 \times .875}{72 \times 5} = 113 \text{ pounds}$$

Assuming the horse-power of a 66 in. by 16 ft. boiler to be the same as the horse-power of a 72 in. by 14 ft. boiler—

*Second of a series of articles on this subject.

**Copyright by the MacLean Publishing Company.

and many boiler manufacturers have them so rated—the 66 in. by 16 ft. boiler would be cheaper as to first costs and ordinarily would be a better steamer than the 72 in. by 14 ft. boiler; and being a better steamer would not consume as much fuel.



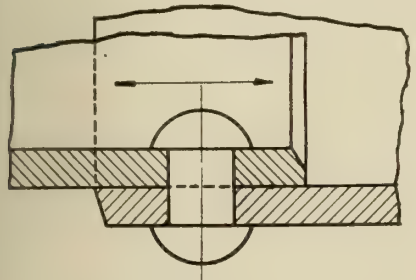


Fig. 10.

The chief reason why the 72 in. by 14 ft. boiler would cost as much and perhaps more than a 66 in. by 16 ft. boiler, is due to the fact that the former will ordinarily be constructed with a shell plate at least 1-16 inch heavier than the latter; also, the former boiler will require more tubes than the latter,

Fig. 11.

and a little more work in the way of drilling flue holes, rolling flues, etc. The total costs of the respective boilers will not, however, be a great differential.

The question has been asked more than once as to why Marine Boilers are constructed ten feet and more in diameter, while tubular boilers are rarely made greater in diameter than seven feet. The reason why Marine Boilers can be made large, having shell plates from one in. to one and one-half in. in thickness, is due to the fact that the shell plates are not in contact with the flames and hot gases.

The better part, one-half or more, of the shell of a tubular boiler is in contact with the flames and hot gases, and is a part of the heating surface of the boiler.

Fire-Cracks.

(10) The heavier the plate the more liable it is to become overheated. This is especially true if foreign substances are allowed to adhere to the plate. Frequently the plate of the girth seams of a tubular boiler crack from the rivet hole to the edge of the plate, as shown in Fig. 7, which is spoken of as fire-cracks.

This is due to the plate only being indirectly cooled by the water within the boiler; hence, it becomes semi-overheated, setting up stresses which crack the plate. The cracks are not serious—that is, dangerous, unless there are many such cracks. If, however, the crack extends into the solid plate, then take steps at once to prevent the crack from extending itself.

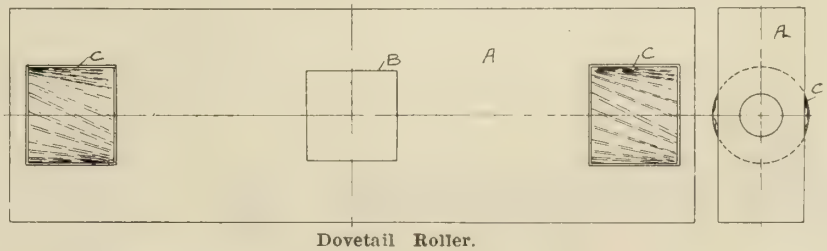
The girth seam of a tubular boiler directly over the bridge wall, as shown in Fig. 6, usually receives the impinging flame and due to the double thickness of metal, as well as the rivet heads, the metal at this point is many degrees hotter than at other points, resulting in fire-cracks.

Fire-cracks are frequently calked over and remain steam-tight. Sometimes they become troublesome and are taken care of by chipping out and calking, as shown in Fig. 8. Of late some manufacturers, who have adopted the two-course tubular boiler type of construction, are now driving the rivets in the lower part of the girth seam as shown in Fig. 9. This, however, they are limiting to just the girth seam over the bridge wall and about two feet up on each side of the boiler.

It is possible for the boiler designer with some types of boilers to design the boiler lines to prevent undue cracking of the plate from the rivet holes to the calking edge.

This can be done with the furnace of locomotive type boilers. The practice is to bevel the door sheet and the flue sheet, especially the latter, for it is the heavier of those composing the furnace, in the manner shown in Fig. 10.

The rivet holes are countersunk and the rivets driven with an oval countersunk head on the side in contact with the flames and hot gases. The beveling of the plate and the installation of the rivets with oval head is for the purpose of having as little metal as possible indirectly cooled by the water within the boiler.



Such a practice is applicable with the furnace of the locomotive type boiler, for the force acting on the furnace acts as indicated by arrow, Fig. 10, and thus the plate from the centre of the rivet hole to the edge of the plate has no force acting upon it, while the plate from the centre of the rivet hole to the edge of the plate of the girth seam of a tubular, the same being indicated in Fig. 11, has to resist the force acting upon the transverse plane of the vessel.

The distance from the centre of the rivet hole to the edge of the plate with the girth seam of a tubular boiler should be one and one-half times the diameter of the rivet hole, while the distance a, Fig. 10, can be considerably less—usually about 1 1-8 times the diameter of the rivet hole—and, because of the action of the force as described.

DOVETAIL ROLLER.

In the old style gate valve made by the Canada Foundry Co., Toronto, the wedge or gate is made of cast iron with brass facing. This brass facing piece is dovetailed into the cast iron wedge, by a circular dovetailing groove. Because of its form, it is impossible to fit them together because of the bottom of the dovetail groove being greater in diameter than the top. For that reason, other means are used. The two contact faces of both wedge and facing are machined, so that the facing will drop into the recess in the wedge. By means of the rollers shown in the accompanying sketch, the brass of the facing, is forced outward into the dovetail groove, making a solid union between the two. The face is afterwards machined to give the bearing surface.

The manner of operating the rollers is as follows: The plate A of which the

Dovetail Roller.

rollers consist, is placed on a square piece in the tool post, and over which hole B fits. The tool post is centralized and pressure brought to bear on it shoving the two hardened steel rollers C against the brass. The rollers are corrugated, which, added to the pressure, forces the brass outward into the dovetail groove.

Mechanical Drawing and Sketching for Machinists*

By B. P.

A Series of Progressive Lessons Designed to Familiarize Mechanics With the Use of the Apparatus Necessary to Make Simple Drawings, to Encourage them to Realize How Important a Factor it is of Their Equipment, as Well as Being a Profitable Pastime.

AN accessory to progress and good drawing work is a reliable equipment of tools. This need not be too expensive unless the aim is ultimate daily use in a drawing office. The various items described are such as will be found at least sufficient for the course as already outlined.

Apparatus and Applications.

The first necessary requirement is a drawing board, and this should be as large as can be conveniently handled in

Fig. 2 Drawing Board.

an ordinary furnished room. Sizes 17 by 24 inches minimum to 23 by 32 inches maximum will in most cases be found suitable. Fig. 1 in our first article of the series showed an adjustable board and table combined, while Fig 2 shows a simple board for use on a table or bench

The drawing board should be located where you have the benefit of a good light and your relation to it such that the light strikes the work from the left hand top corner. To realize the full effect on your paper, the light should be shaded, and to obviate excessive stooping the board should be placed conveniently high and slightly sloped toward you care being taken that the slope is not so great as to cause your tools to roll or slide off.

The drawing paper should be bought in sheets of sizes 15 by 20 inches and 22 by 30 inches respectively to suit the drawing boards already referred to and ensure no overlap beyond the board edges. Paper used of the full size of

drawing board may run just over the edge on which the head of the tee square slides and does not therefore give a truly square line to that edge. When overhanging the other edges it invariably gets ragged and inclines to tear in on the work.

Drawing sheets are not usually perfectly square edge to edge, therefore when fixing to your drawing board see that the edge next the tee square head or left hand is parallel with that edge of the board.

Fig. 5 –Bale Head Drawing Tacks.

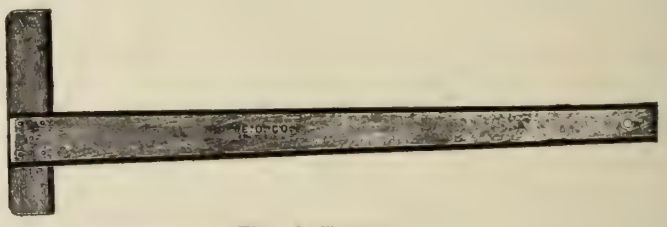


Fig. 6—T-square.

For practice purposes good paper is indispensable and Whatman's hot pressed demy and imperial are recommended.

Regular drawing office work admits of very inferior quality of paper being used, the reasons being that the draftsman is usually expert enough to treat it tenderly while making use of it and that immediately the tracing copy is made the drawing sheet finds a resting place in the waste paper basket. You, if a beginner, would experience much disgust with your efforts and their effect on poor quality paper and as it is an intention to minimize your self-abasement as far as possible, good quality paper in your hands becomes a necessity.

Figs. 3-4-5 illustrate various styles and sizes of drawing tacks, those with the bevelled edges, Fig. 3, being perhaps the most suitable at a diameter of ½-inch. One tack should be placed at each corner about ½-inch in from the edges of the paper and a further tack placed at the lower edge about the middle of the paper length, also ½-inch in from the edge of the paper. Tacks should never be placed on the left or right hand edges intermediate to those at the corners as they interfere with the movement of the tee square and tend to chew its edge. The drawing paper should be drawn flat and tight when being tacked to the board.

The tee square, Fig. 6, should be at least the length of the drawing board between the inside of head and point and should not exceed that distance, if possible for convenience. A tapered blade as shown gives usually a better balanced tool and excess length upper part head over the lower should be a feature. This admits of the tee square being operated close down to the lower edge of the sheet without danger of the horizontal lines being out of square with the left hand edge of the board through insufficient bearing surface of head. The drawing edge must never be used for cutting paper.

The tee square should be hung up by the hole in blade when not in use and in the case of it falling to the floor accidentally at any time, a line previously drawn by it on the board and used as a setting standard should be taken to re-

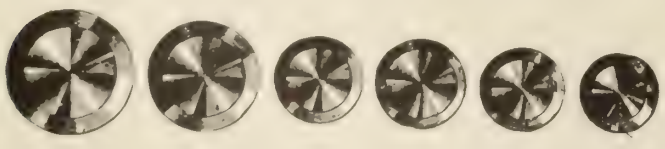

Fig. 3 Bevel Head Drawing Tacks.

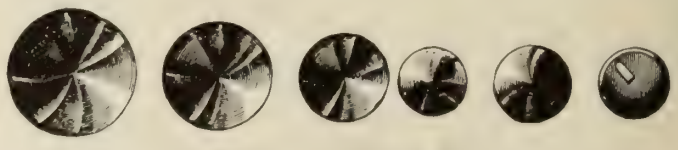

Fig. 4—Stamped Drawing Tacks.

set the blade if it has shifted.

The purpose of the tee square is the drawing of right angled horizontal lines, and the forming of a base on which the triangles or set squares rest when vertical or angular lines are required.

*Second of a series of an Instruction Course. A lesson will be given each month.

NEW UNITED STATES STEEL PENSION PLAN.

Plans have been consummated to pay pensions from the United States Steel and Carnegie Pension Fund, which was established last spring by the joint action of the United States Steel Corporation and Andrew Carnegie. This fund was established for the purpose of paying old age pensions from the income of the fund to employes of the United States Steel Corporation and its subsidiary companies. For this purpose the United States Steel Corporation provided eight million dollars, which, with the Carnegie Relief Fund of four million dollars, created by Andrew Carnegie on March 12, 1901, makes up a joint fund of twelve million dollars. This pension fund is administered by a board of twelve trustees, through a manager appointed by the board, with such powers and duties as may be given him by the board.

The Board of Trustees has adopted pension rules for the administration of this fund, to take effect on January 1, 1911, and apply to persons who are in the service of the United States Steel Corporation and its subsidiary companies on and after that date.

Under the pension rules three classes of pensions are provided :

First—Pensions by compulsory retirement, granted to employes who have been twenty years or longer in the service and have reached the age of seventy years for men and sixty years for women.

Second—Pensions by retirement at request, granted to employes who have been twenty years or longer in the service and have reached the age of sixty years for men and fifty years for women.

Third—Pensions for permanent incapacity, granted to employes who have been twenty years or longer in the service and have become permanently totally incapacitated through no fault of their own.

The monthly pensions to be paid from the income of the fund will be made up on the following basis. For each year of service 1 per cent. of the average regular monthly pay received during the last ten years of service ; provided, however, that no pension shall be more than $100 a month or less than $12 a month. For example, an employe who has been 25 years in the service and has received an average regular monthly pay of $60 a month will receive a pension allowance of $15 a month.

This pension fund provides for the support of faithful employes in their old age It is entirely separate and distinct from the voluntary accident relief plan put into operation by the United States Steel Corporation on May 1, 1910, which provides for employes who may be injured and the families of employes who may be killed while at work in the service of the subsidiary companies of the United States Steel Corporation.

Neither the voluntary accident relief plan nor the United States Steel and Carnegie pension fund involves any contribution from the men themselves toward the accident relief or old age pensions.

Societies and Personal

J. G. Sullivan has been appointed assistant engineer on the C. P. R. with headquarters at Winnipeg.

* * *

J. G. Taylor, heretofore superintendent district 1, Alberta division, C.P.R., Medicine Hat, has been appointed general superintendent Lake Superior division. His headquarters are North Bay.

* * *

H. McDonald, fitter in the C.P.R. Lethbridge shops, Alta., has been appointed shop foreman there.

* * *

M. A. Cardell, heretofore C.P.R. shop foreman at Lethbridge, Alta., has been appointed shop foreman at Medicine Hat, Alta., vice J. McQuarrie, appointed locomotive foreman at Sutherland, Sask.

* * *

Peterboro Lodge, 286 of Machinists, held an anniversary night on Jan. 26, when a social time was spent.

* * *

The Canadian Railway Club, Montreal, meets at the Windsor Hotel, on March 7, when a paper will be presented by L. R. Clausen, Divisional Supt. of the C. M. & St. P. Ry., Chicago, Ill., on the subject of "Railway Signalling."

* * *

Thos. Arnold, vice-pres. Taylor & Arnold, Montreal ; D. A. Evans, draftsman, G. T. P. shops, Winnipeg ; and Clifford Walker, Taylor & Arnold, Winnipeg, have been elected members of the Western Canada Railway Club, Winnipeg.

* * *

The McLaughlin Carriage and Motor Car Companies, Oshawa, held an Employes' Ball on Jan. 24, in one of the wings of the new automobile works. The ball was a success from every point of view, due to the efficient management of this committee : H. Cook, B. McCabe, W. Haynes, N. Hall, A. Moffatt, A. Brownley, M. Parker, G. Johnston, J. H. Beaton, A. McClure, J. B. McCullough, Mr. Waters, W. A. Coad, G. C. McKeen, E. Hamilton, Ed. Michael, H. Hagerman and Jack Crawford. The 500 guests were addressed by Robt. McLaughlin early in the evening.

* * *

St. Thomas machinists held the first annual ball in the Engineers' Building, St. Thomas, on Feb. 16. The master of ceremonies was John Fitzpatrick. The committee was composed of John Lane, chairman; W. E. Moore, secretary-treasurer; J. W. S. Booth, J. H. Gray, T. Stone, Frank Clark, John I. Stewart, W. Follick, Wm. Bortman and P. G. Erickson.

* * *

The Alberta Wholesale Implement and Carriage Dealers' Association held its annual meeting Feb. 4, in Calgary. The officers for 1911 are:—President, J. A. Latimer, Cockshutt Plow Co.; first vice-pres., S. H. Roe, Tudhope, Anderson & Co. ; second vice-pres., L. P. Winslow ; Ontario Wind Engine and Pump Co.; treas., A. W. Trickey, Massey-Harris Co.; sec'y, W. E. Hall, Cockshutt Plow Co. ; Executive Committee, J. A. Brookbank, International Harvester Co.; A. W. Trickey; F. T. Wright, Canadian Moline Plow Co.; J. Ruttle, McLaughlin Carriage Co.; O. S. Chapin, Chapin Co.; P. D. McLaren, Canadian Fairbanks.

* * *

Librarian Carson of the London Public Library, has been giving lectures at the G. T. R. shops, McClary's, and other shops and foundries in London, drawing the attention of mechanics to books in the library of interest to them.

* * *

The first of a series of social affairs to bring the C.N.R. and C.P.R. machinists together was held Feb. 17 in the Odd Fellows' temple. The evening started with a reception at 8 o'clock and a concert at 8.30, which included many interesting numbers together with a short talk by A. W. Puttee who acted as chairman of the concert programme. Following the entertainment programme there was a luncheon which in turn was followed by dancing. A joint committee was in charge consisting of the following:—E. Pearson, chairman; W. J. Paterson, secretary, and A. Gamble, M.C.; G. Douglas, D. McCullough, G. Johnston, H. McDonald, S. Miller, M. H. MacGregor, A. Pentland, J. Mountjoy, F. Pratt, A. Kain, R. F. Ward, J. G. MacFadden, G. Smith, and A. R. McEwen.

* * *

Lumen P. Sherwood, Peterboro, in a competitive examination, won the position of chief assistant of the Department of Railways and Canals, Ottawa.

* * *

J. F. I. Thomas, M.I. Mech. E., A.M. Inst. C.E., representing the electrical department of Vickers Sons and Maxim, Sheffield, England, spent a few days in Toronto recently on his way from England to Winnipeg. He goes to the prairie city to supervise the installation of the electrical equipment being supplied by his firm for the municipal hydro-electric works, Point du Bois Falls, Winnipeg River, Winnipeg, Manitoba.

J. M. Burke district master mechanic C.P.R. district No. 1 Atlantic division with headquarters at Brownville Jct., Me., has been appointed master mechanic eastern division with headquarters at Smith's Falls, Ont.

* * *

Paul J. Myler, vice-president Canadian Westinghouse Co., Hamilton, has been elected president of the Ontario Motor League.

* * *

W. E. Barnes, roundhouse and locomotive inspector, Moncton, N.B., has been appointed master mechanic eastern division, I.C.R., with headquarters at Moncton.

* * *

T. Ross has been appointed master mechanic of the T. & N. O. Ry., with headquarters at North Bay.

* * *

George H. Wadsworth, for the past 15 years superintendent of the Falls Rivet & Machine Co., Cuyahoga Falls, Ohio, has resigned that position, and will on and after March 1 devote his entire time to the Wadsworth Core Machine & Equipment Co., Akron, Ohio. He has purchased all machinery, patterns, tools and interest from the Falls Clutch & Machinery Co., successor to the Falls Rivet & Machine Co. for the manufacture of the Wadsworth core machine and equipment as manufactured by that company during the last seven years for him.

* * *

Wm. C. Mitchell, formerly superintendent of the Dominion Steel Co., has opened an office in the Canadian Express Building, Montreal, as a consulting engineer. Mr. Mitchell is prepared to undertake the design of modern iron and steel plants, and the securing of economies in existing plants.

* * *

J. T. Brower, of the Structural Steel Co., Longue Point, Que., has been appointed general manager of the National Bridge Co., Montreal.

* * *

Frank Walker, formerly of the C. P.R. at Smith's Falls, has been appointed foreman of general repairs for the New Glasgow plant of the Nova Scotia Steel & Coal Co.

* * *

S. S. Underwood, chief draughtsman G.T.R. Car Department, Montreal, was presented recently, with a fitted traveling bag, and a brooch for his wife, by the staff, on his leaving the service, to enter that of Taylor & Arnold, dealers in railway equipment and supplies, Montreal and Winnipeg.

* * *

The Master Car Builders' Association meets in Atlantic City, June 19-21; the Railway Supply Mfrs. Association, June 14-21, and the American Railway Master Mechanics' Association June 14-16.

* * *

A. W. Horsey, formerly master mechanic eastern division C.P.R., with headquarters at Smith's Falls, Ont., has been appointed district master mechanic district No. 1 vice D. L. Jones transferred to the Atlantic division. His headquarters will be at Farnham, P.Q.

* * *

H. Smith, formerly superintendent of the Canadian Crocker Wheeler Co., St. Catharines, has accepted a position with the Canada Foundry, Toronto.

* * *

Edward Blake, jr., manager of sales for the Wells Brothers Co., Greenfield, Mass., for the past four years, and a director of the corporation, severed his connection with the company Feb 1. He has obtained the controlling interest in the Canadian Tap & Die Co., Galt, Ont., of which he has been trasurer since its organization in 1905. He has taken the active management of the company's affairs and will devote his entire time to promoting its business. Mr. Blake came from the west nine years ago to enter the employ of the Wells Brothers Co. as a stock clerk and acquired a thorough knowledge of the entire line of Little Giant screw thread cutting tools and machinery, which was of great value in his later work. He was promoted to the order department, and from there went through the various departments of the offices to the desk of sales manager and manager of the offices. His work in this capacity was eminently successful and in 1909 he was elected a director.

* * *

The Late Robert McDougall, Galt.

Robert McDougall, the founder of the R. McDougall Co., Galt, died on Feb. 17, at the age of 86. He was born in Roxboroughshire, Scotland, and was a resident of Galt for 60 years. In the early seventies he and his brother Thomas, commenced to manufacture iron pumps and windmills. Now the lines manufactured include metal and wood working machinery, pumps, etc., a specialty being metal working lathes.

* * *

P. J. Smith Banqueted.

Hotel Quinte, Belleville's famous hostelry, was the scene of a splendid banquet recently, when the business men of the town, assembled to bid farewell to P. J. Smith, who is removing to Winnipeg.

For the past four years and a half, Mr. Smith has been superintendent of the Canada Bolt and Nut Co.'s Rolling Mills at Belleville, which he has brought to a high state of efficiency. He was recently appointed manager of the Manitoba Rolling Mills, at Winnipeg, and his leaving to assume that position, was made the occasion of this unique banquet.

W. B. Deacon, president of the Board of Trade, acted as chairman, and splendid speeches were made by many of Belleville's most prominent citizens.

P. J. SMITH.

In response to the toast "Our Guest," Mr. Smith, foretold prosperity and business expansion for Belleville. He urged the business men of the city to work for better transportation facilities both by rail and water. This, he thought, would result in making Belleville an industrial centre.

That the banquet was such a huge success, was due largely to the efforts of Ald. R. C. Chown, who responded to the toast of the "City of Belleville."

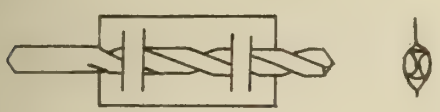
* * *

CANADIAN BRANCH BRITISH MANUFACTURERS.

The associated firms of W. T. Glover & Co., Royce, The Howard Asphalt and Troughing Co., The Ashover Fluor Spar Mining Co., all of Manchester, England, have secured offices in the Lumsden Building, Toronto, for the purpose of direct representation on and supply to the Canadian market of the various specialities produced and manufactured by them. These latter consist of underground cables and wires, electric cranes, and direct current motors and dynamos, asphalt troughing for underground conduits and fluor spar for steel smelting.

C. S. Mallett who will be in charge and manage the Canadian business is renewing his connection with the Dominion after an absence of 12 years, all of which time he spent at the various firms' headquarters he now represents.

The scope of the business to be undertaken will include reporting and advising as to the best and most suitable equipment required, the supply, delivery and erection supervision of same and the furnishing of prompt and complete tenders, plans and specifications.



MACHINE SHOP METHODS AND DEVICES

Unique Ways of Doing Things in the Machine Shop. Readers' Opinions Concerning Shop Practice. Data for Machinists. Contributions paid for.

DRILLING KINK.

By G. B. Marquette.

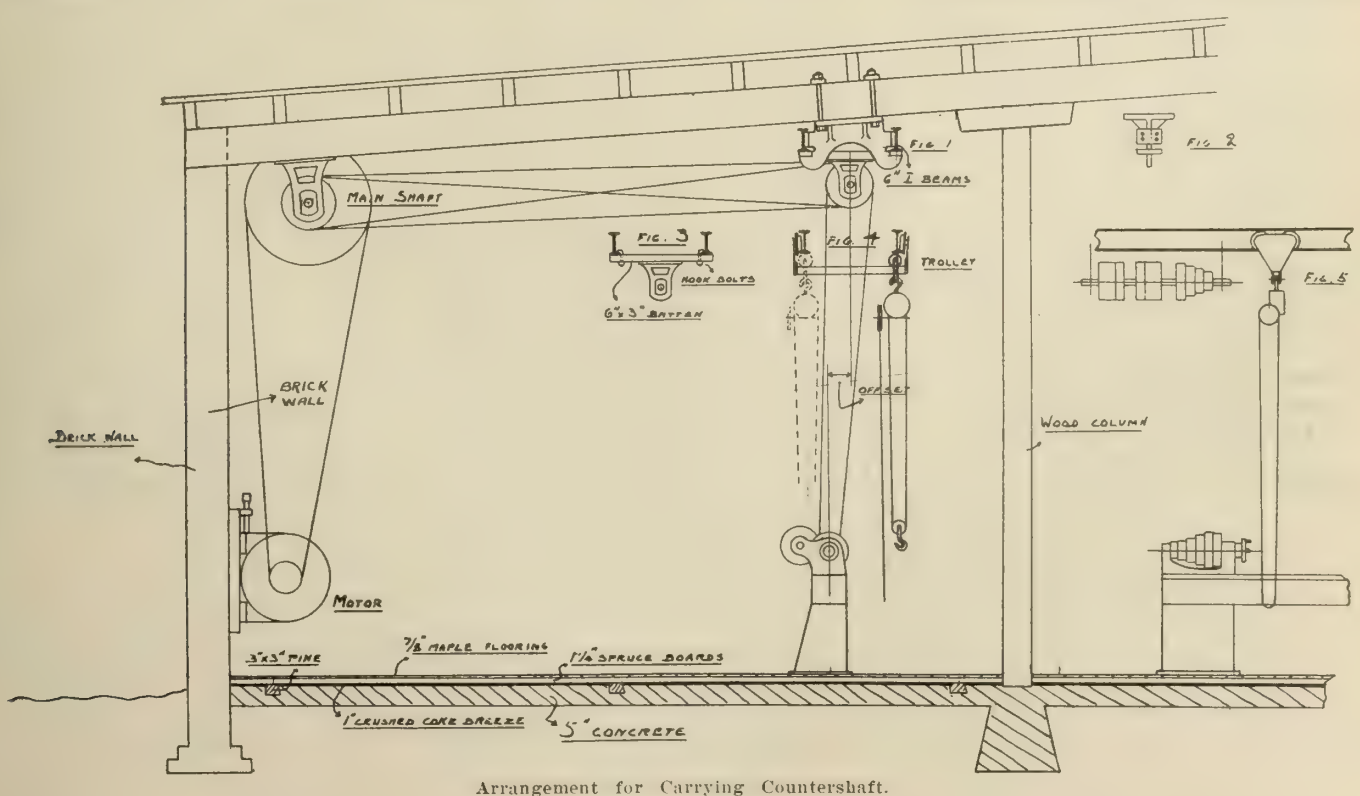
In drilling a large number of holes close together, the chips and cuttings from the holes being drilled completely cover up the marks (lines and centre punch marks) of the next holes to be drilled, necessitating the operator to stop and blow or clear the cuttings away, before he can locate the next hole. If we take a piece of tin and cut

Removing Drill Chips.

two slits as per sketch and then pry the slit up as seen in end view, we can pass the drill through the two slits and it will be found tight enough to revolve with the drill. When the drill has completed the hole, we lower the drill until tin touches the work when the heavy cuttings will be brushed off while the finer dust will be fanned off by the rapidly revolving piece of tin, leaving the work clear, and the next hole centre easily located.

SUPPORTING COUNTERSHAFT.

By H. Smith.



This sketch shows a convenient method of supporting countershaft gear from roof and has the advantage that it can be used in conjunction with a trolley and chain block for lifting work in and out of the machines. Steel I beams are carried over the line of machines by means of cast-iron brackets which are bolted to the roof beams. See Figs. 1 and 2. These beams for ordinary machine shops should be 26 in. to 30 in. apart and their depth will depend on the span between the roof beams, 6 in. for a 14 ft and 8 in. for a 16 ft. span being adequate. They must run the full length of the line of machines to be driven. Their centre line is offset from that of the machines so that the trolley has its range in front of the latter, enabling, say a lathe operator to pick up a heavy job from the floor and slide it into the centres without having to obtain the help of a couple of men to guide it in for him.

The countershaft hangers are bolted to wood battens which are readily placed in position on the steel beams by hook bolts. See Fig. 3.

The main driving pulleys on the countershafts are placed in the case of a lathe to the left of the headstock so that the trolley has a range of action the full length of bed in one direction and the distance between beam centres in the other. See Figs. 4 and 5. The whole arrangement has a neat appearance and saves time both in setting up machines and later in handling work too heavy to lift by hand.

Shop Floor.

The sketch also shows a first-class floor for a shop where moderately heavy work is handled, say up to 2 tons. The earth is levelled off and well tramped down before laying the 5 in. of concrete; 3 in. by 3 in. battens are laid in this, the length of shop and about 8 feet apart. These battens are bevelled as shown so that they have no tendency to pull out of the concrete and stand up 1 in. from the face of the latter. Crushed breeze is then rolled onto the surface of concrete when set and levelled off by means of straight edge from batten to batten; 1 1-4 in. spruce boards unplaned, but sawn equal in thickness, are then nailed to battens in a cross direction. Finally hard maple flooring, tongue and grooved, is laid, leaving a good level surface provided the underneath work has been properly carried out. This flooring will

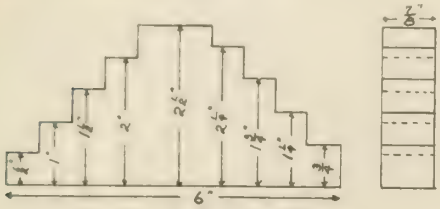
Arrangement for Carrying Countershaft.

not splinter and has a certain amount of spring in it, due to the spruce underboards and coke breeze. The latter also allows for a certain amount of ventilation which is further amplified by the maple flooring boards being grooved underneath. There is no danger of dry rot setting in and castings dropped onto it are not so liable to break as on a bare concrete floor. It is easy on the operator's feet.

DISTANCE GAUGES.

By G. B Marquette.

An addition to the tool store are the "distance gauges" as per sketches. A great variety can be made, a combination of which will give any required di-



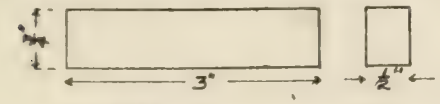


Fig. 1—A Distance Gauge.

mension. They can be made very cheaply (an apprentice could handle the job in the tool room) and the first cost is quickly returned by the rapidity with which a tool can be set to the required depth. The operator KNOWS without stopping to check the cut, that he has the given dimensions, and that it is RIGHT.

The apprentice could get them within grinding limits and stamp them, then harden and grind.

Fig. 1 shows a distance gauge and Fig. 2 the application of one. Referring to Fig. 2, the gauge is hardened and

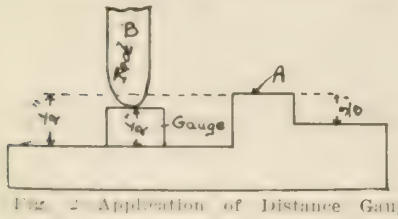

Fig. 2—Application of Distance Gauge.

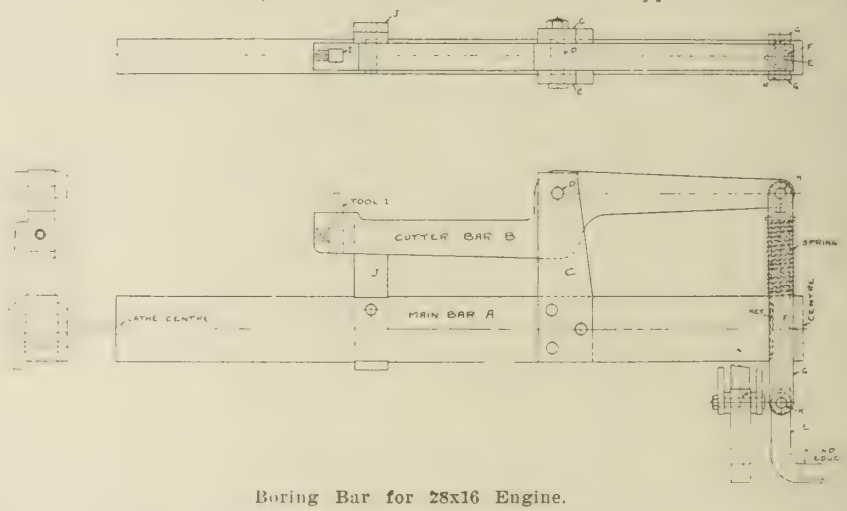
ground. B is the tool and a chip must be taken from A to bring it down to the thickness shown by the gauge.



BORING BAR FOR ELLIPTIC CYLINDER.

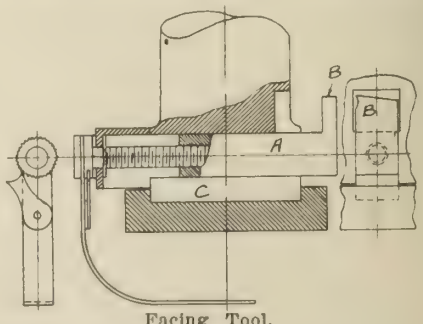
The accompanying sketch shows a boring bar used in the works of the John Inglis Co., Toronto, for boring elliptic cylinders, and which can be used for boring cylinders of any shape.

The firm, in producing some cylinders for a special job—cylinders which were neither oval nor of the form of separated circular segments, in shape, were confronted with the proposition of machining. A tool something along the lines shown was made, but discarded in favor of this latter bar, devised by G. E. Fax, draftsman for the company.

The construction is as follows: A main bar A, swinging between lathe centres, the right on the tail-stock centre and the left on the head-stock, has a cutter bar B, attached to it by a double arm C, projecting from bar A, and this bar B is pivoted on C, by fulcrum pin D.

At the right-hand end, a square bar E, bent at its lower end, and turned on its upper portion, passes through a reamed hole F in bar A. This hole F has a key-way with corresponding key in E to prevent twisting of the part. Straps G straddling A, connect rod E through pin K to bar B through pin H. The lower end of rod E, which, as before mentioned, is bent, shaped approximately knife-edged, to follow a contour. On the tail spindle a form exactly the same in shape as the bore of the cylinder, is secured, and the edge at the lower end of E follows this, and causes

Boring Bar for 28x16 Engine.



the tool I to follow the same motion, boring the cylinder the same shape as the guide. The spring on E causes the edge to follow the guide closely. The bore is the same as the guide, not only in shape, but in size, as the distance from D to H is the same as from D to I. Projecting piece J takes the strain of the cut, causing H.D. and the tip of I to be in a line parallel to the bar A and makes the motion very nearly perfectly true, the only error being that due to the slight angularity of the pin H at its extreme positions. The former bar made did not reproduce the desired shape so accurately, as the construction was somewhat different. Suppose the tool I to remain where it is, and the bar B to be across the main bar A, so that the tips of B at H would be at K. This cutter bar B would thus be diagonally across main bar A, and as the follower edge would move vertically, and the tool I in a circle, the motion would be distorted. This was practically overcome by having an off-set tool at I, turned to the left, so that the more the motion was distorted due to angularity, it would be compensated for by the tool digging in further.

FACING TOOL.

The accompanying sketch is of a handy facing tool made use of by Wm. Kennedy & Sons, Owen Sound, for facing of bolt holes in propeller hubs, flanges, and similar positions. The usual methods of using a flat cutter is familiar to all. Its principal objection lies in the fact that its whole cutting face strikes the hard scale first, removing the cutting edge before any material progress is made.

The facing tool here shown, operates on the principle of a cross cut bar, with a plain gooseneck tool, shown at A. The end B is bent up to form the gooseneck B, which forms the cutting edge. This tool is contained in a slot in the end of the usual type of bolt hole fac-

ing bar, and slides crosswise on strip C the whole being held in position by four cap screws in cap D. The tool A is tapped as shown, and a ratchet screw

Facing Tool.

feeds the tool across, giving the necessary cut. The beauty of the tool lies in its ability to keep below the hard skin, and thus save the tool.

This principle has been used by the company for the last 20 years giving great satisfaction.

Correspondence

Comments on articles appearing in Canadian Machinery will be cheerfully welcomed and letters containing useful ideas will be paid for.

Information regarding manufacturers of various lines, with their addresses will be supplied either through these columns or by letter, on request. Address letters to Canadian Machinery, 143-149 University Ave., Toronto.—Editor.

* * *

Tapping Hole Straight.

The correct answer to the question on tapping a hole through a sphere is as follows: Secure a faced nut over the tap and down against the work. If it touches all around, it indicates that the tap is going in straight.—Apprentice.

* * *

Tinning Cast Iron Cross-Head Slippers.

Will some of the readers of Canadian Machinery give me a method for tinning cross-head slippers in quantities so they can be planed.—W. A. T.

LONG LATHE WORK.

That word "long" in the title is used relatively—long in proportion to the lathe. A clever method of doing such work is by "splicing" two lathes to take in long bars as described in December issue of Canadian Machinery, p. 47. Most of us have seen or have worked on lathes having the range extended by means of a planed casting lined up with the original bed and "tie-rodded" to it, and know how seldom such a job is well done or remains accurate for any length of time. For my part, if possible, I prefer to take my chances in one lathe, if the work isn't longer than double the capacity of the lathe, and as an example will relate one job we used to do this way, which had to be finished accurately.

In Fig. 1 is shown a roller having journals at the ends and driven from one end, B, which occasionally twisted off at A under an extra heavy strain. These rollers, new, were 2 1-16 in. diameter, and, as they wore, were turned down to 1 15-16 in., the limit of adjustment in the machine in which they were used. They were brought to us to be dressed up, and we usually had to reduce them 1-32 in. in diameter to clean up the low spots. Our longest lathe was shorter than the rollers by about 2 feet, which meant that we had to reverse them to turn the body proper, and had to resort to some expedient when the journals had to be renewed; sometimes we had a combination of both jobs to do at one time.

Considering first the broken journal, we commenced by setting the jaws of the steady rest to an arbor between the centres of the diameter of the body of the roller. After that the tail stock was taken off the lathe and the rest moved to the extreme end of the ways. The other, or broken, end of the roller was clamped in a V-block on the cross slide of the carriage and lined up with calipers approximately true with the ways, and the same as the end in the steady rest which was already centred. Then with a drill in the universal chuck the end was drilled out and into the hole was driven one end of a bar of steel and pinned. To turn a new journal, on this inserted bar, its free end was gripped in the chuck, and the roller turned up to within 1-1000 in. at the part nearest to the journal to be. It will be noticed that the bar was left long enough to be turned, threaded, and cut off outside of the chuck.

This is, I think, about the most satisfactory way of turning and threading on the end of work longer than the machine; at one time I had a lot of 12 in. pipe to cut off and thread, and did it by cutting the pieces about 4 in. longer than the made-up length, threading to a caliper fit, and cutting off with the cut-off tool.

To return to the roll turning job, it can be imagined that when cleaning up the body—with a cut never exceeding 1-64 in. deep—trouble would be experienced from chattering. We proceeded as follows: one end was chucked on the journal and the best portion of the roll proper turned up with an indicator. The steady rest (set first to an arbor) was used to support the other end of the roller, and was set on the best spot, near the end of the lathe, which usually left from 2 to 3 feet projecting.

As to the cut, we started in close up to the steady rest with a fine round-nosed tool having plenty of rake and running with a fine feed. After the cut had moved up toward the headstock 12 in. to 15 in., it would show signs of chattering when we would apply a second steady rest as near the end of the new cut as the carriage would permit, and proceed as before, moving this "following steady rest" every foot or so. After turning the major part of the roll, which was on the lathe, it was reversed, set in the steady rest, and centered by the chuck till the newly turned portion was true.

We found the second steady rest superior to a follow rest for the reason that the work was held in all directions, while with the follow rest the sag toward the center of the unsupported portion of the roll was considerable, and the cut was not heavy enough to keep it up against the jaws.

It was necessary to turn the rollers to within 1-1000 in., for which a micrometer was invaluable. We finished with a fine file and polished with No. 00 emery cloth. This gave us a surface equal to the ground finish on the rolls when they were new, and fully as accurate. Sometimes the rolls would show an almost fiendish tendency to chatter, and we fell back on a flat-nosed tool with top rake only, setting it so it cut on the side next the headstock only, and clear a 1-32 in. on the other side of the front edge.

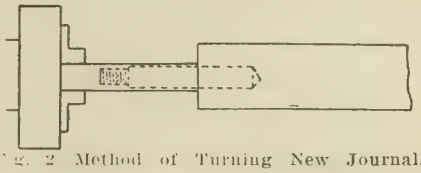


Fig. 2 Method of Turning New Journal.

Those who have accurate turning of this nature will find the above method a little slow, perhaps, but sure. I prefer it to a built-on lathe, if the work is short enough, but must admit its inferiority to the "double" lathe mentioned at the beginning of this article, or one good long lathe.—D. A. Hampson.

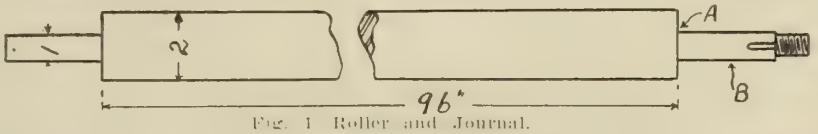

Fig. 1 Roller and Journal.

A centrifugal oil separator paid for itself in sixty days in a watch factory. It is used to clean superfluous oil from the work and to separate oil from waste. The oil is used over again.

The superintendent of an insulated wire factory, which employes a great number of women operatives, has established a noon lunch room where a meal, including soup, meat and a dessert, may be purchased for thirteen cents. The restaurant is in charge of a local caterer and the figure given covers the cost of the meals.

The Iron Trade Review recently called attention to the fact that motors installed in machine shops are frequently too large, owing to the fact that the exact amount of power required is not definitely known. As a motor is most efficient at full load, the result is that there is an undue loss of efficiency. A number of cases are cited wherein the exact amount of power required was determined by means of volt meter and ammeter readings, showing that the motor in use was of too high a power, and after this motor was replaced with one of the required power, a considerable economy of power was effected.

Vol. VII. March, 1911 No. 3

"DIGGING."

Efficiency campaigns have been carried on and much written on the subject. It is known as "good management" or "scientific management" but it really amounts to the same thing—"digging," that is, working for the best work in the quickest time, at the lowest cost, with good wages to the producers of these results.

The United States Interstate Commerce Commission has brought to light systems of management by which the output of the plant has been increased, not by increasing the equipment or the number of workmen but by investigating existent conditions and making changes which result in greater economies and enable the company to increase the dividends and pay better wages to their employes.

There can be no objection to the statement: "To get the best results from men, offer inducements commensurate with the cost to them of maximum effort." The healthy human has no objections to work if it is made pleasant for him and he is paid at least market value for his efforts.

It is gratifying to note that the reduction in costs of manufacturing has been done without reducing wages. In fact, experienced organizers provide for largely increased wages to efficient workmen who put forth their best efforts. This is done by means of a piece-work or premium system which stimulates effort and rewards the efficient workmen.

There are other means by which costs have been reduced and are reduced. It calls for investigation—or digging—to bring them to light, but it pays. In the Feb. issue appeared an article on Scientific Management—what it is and what it will do. It pays to get away from the "rule o' thumb" method of doing things whether in the drafting room, manager's office, foremen's office or in the workshop.

The buying department also calls for some "digging." It is well to use a magnifying glass or a microscope occasionally and search for the little leaks. Recently we learned of one company that is losing thousands of dollars in buying alone. A "rank outsider" discovered it.

One firm was building its own special machinery. A little "digging" revealed that a company specially equipped for such work would have built the same machines for 25 per cent. less.

Another firm was throwing away the small ends of high speed steel cutters and drills, but it was discovered by a foreman that these could be used to advantage by using the pieces as tips for tools. The method was practically that given in "Efficiency of Tools and Economy in their manufacture" in the February issue.

A number of pertinent questions are asked in the article on "What is Scientific Management," that are worth studying. They should lead to "digging" for leaks in your plant. A vigorous search will reveal unthought of leaks. One small Toronto factory saved $11,400 in a year by scientific management. Reports are continuously being brought to light of leaks stopped and the shop being brought to a higher state of efficiency, all accomplished by "digging."

MACHINE TOOL COMPLAINTS.

The article in our present issue entitled "Machine Tool Manufacture—Quality and Guarantee" is worthy the attention of and careful reading by all users of these commodities. The purchase of a machine tool or in fact anything from a reputable maker should be recognized as something beyond a mere monetary transaction. It should be, and really is, the assistance which one man gives another in the highest and best sense, enabling each to do more perfectly in combination, that which neither could perform as well individually.

The guarantees and advices given users by manufacturers have a real cash value to both, and the sentiments expressed in "Penstock's" paper merit the practical emulation of all producers and appreciative regard of all operators. Machine tool manufacture and operation have reached a high pitch of excellence, to maintain and surpass which must needs demand the helpful co-operation of both parties interested.

THE QUEBEC BRIDGE.

For the second time since the Quebec Bridge Commission has had the plans of a new bridge under consideration, experts have been called in to settle a difference which has arisen between the members of the board on engineering points. The immediate trouble, says a Montreal paper, is that engineers Modjeska and Macdonald favor the St. Lawrence Bridge Co. tender on its own plans, while engineer Vautelet favors the Empire Bridge Co. tender on the board's plans.

In the face of this statement we cannot help sympathising with the minority and complimenting it on its pluck and confidence.

Much good public money has been spent by this commission in the preparation of plans and specifications, which seems might have been saved if builders' plans are better, more trustworthy and necessary of acceptance.

From whatever standpoint looked from, the necessitous acceptance of the majority recommendation seems to us a reflection on the commission's work, and a certain robbing of a signal world-honor from it.

On the other hand it stamps the designer staff of our St. Lawrence Bridge Co. as a combination whose work

commends itself and whose confidence is not likely to be misplaced.

To engineer Vautelet in his meantime lone stand and in perhaps greater degree, is due also the commendation and public appreciation for a work laid out, his confidence in its stability and usefulness, and his bid for a niche in the temple of fame.

The decision is a momentous one, the more so on account of there being a bridge in the river which like the projected one was intended to span that river.

Bridge designers' and constructors' reputations are at stake, the public safety is involved, the development of our country depends somewhat on it, and money is we presume not being stinted.

Let the best be none too good, let there be a Quebec Bridge, and may its designers receive their due honor.

INVESTIGATION SYSTEM OF PURCHASE.

In the Business Management section of this issue will be found an interesting account of the system of machine tool purchase adopted by a prominent railroad. Pleasing to all engaged in the manufacture and sale of machine tools because ensuring fair competition and recognition of merit, it has also shown profit to those responsible for introducing the system.

Points to be noted are the adaptability of the system not only to other railroads but to manufacturing concerns generally, the quality personnel of the committee, a unit being the superintendent of piecework, and therefore a most appropriate selection to enable that department to be fully efficient.

Such a body gives confidence to the executive that the best available in machine tools is being got for a given outlay and that nothing which can be superseded and scrapped is doing duty on past record. The facilities given to get around and see what is being done by manufacturers admit not only of new and untried specialties being considered, but effectively stops the prejudice and clinging to the well-worn rut so cherished by shop foremen.

Progress and proficiency can only be attained by knowing and seeing what others are doing to help us and recognizing it that way, and any concern that would keep its head in front must nose its way first.

CANADIAN MANUFACTURERS AND EXPORTS.

Some Canadian manufacturers are evidently unfamiliar with methods of extending their export trade. London appears to be the hub of trade and inquiries from all parts of the world are received by the Consulting Engineers and buying merchants in London. United States and German companies, realizing this, take particular care to have their goods known to the merchants in London so that London facilities are offered for the prompt securing of specifications, quotations, etc.

For instance, a firm in India wrote London for information of quotations, etc., on some machinery manufactured in Canada. There was no information available without long delays and a great inconvenience resulted and probably a loss of the order.

Another point in the export trade is the elimination of loose methods in dealing with a foreign purchaser. The Trade and Commerce tells how an order from Japan was lost by one Canadian company because they would not fill the order to suit Japanese conditions. Such a short-sighted policy is harmful not only to that company but to the Canadian manufacturers generally who are looking for an export trade.

WASTES TIME OF MAN AND MACHINE.

On a number of occasions "Canadian Machinery" has drawn the attention of shop foremen, superintendents and managers to the necessity of having sufficient equipment. J. S. Sheafe, Engineer of Tests, Illinois Central R. R., Chicago, Ill., in an article entitled "Care and Selection of Shop Equipment" recently published in "Railway Age Gazette," has the following to say about the use of grinding wheels in railroad shops:

"Have plenty of Grinding Wheels.—Grinding wheels, in most railway shops, are conspicuous by their absence from convenient locations. A machinist would rather continue for a while the use of a slightly dull tool than to bother going, perhaps, the length of the shop and waiting his turn at the wheel. This is hard on the machine, already hard pressed since the advent of high speed steel; also on the work and the man. When it is remembered that the rate of deterioration of a tool when dull does not vary as the work done, but as the square of the work done, there is an abuse all around. Grinding wheels should be placed in all parts of the shop, both machine side and pit side. This makes it inexcusable for a man to work with anything but perfect tools."

A great number of articles included under the heading of "Shop Equipment," may also be included. The above will serve as an example to interest all in keeping the shop at maximum efficiency.

AWAY WITH THEM!

There is too much talk of Ideals. The word is used in sermons and poems and after-dinner speeches. Little souls roll it on the ends of their tongues and lift their mild eyes to Heaven. Surely the truly great have none of them—these ideals.

What is wanted is common decencies—not ideals. The word has too much exquisitely nebulous meaninglessness. Fat men dream of ideals, and in the morning cheat the car conductor. Thin men dream of the same thing and abuse their wives. Lovers think their affinities "ideals," and wake to quarrel about a certain usage in grammar.

There are too many "ideals" and too much self-deceiving. Let us save the word from profanity and hide it until hallowing time has restored its sacred shape, and in the meantime let us collect samples of common decencies, honesty of tongue, and hand, and heart—and put them in a case, lest in a few generations there be none left.

EXPERIENCE AS A TEACHER.

No amount of personal experience can ever make a man perfect. On a few occasions (fortunately they are few) mechanical men have given our subscription men as a reason for not subscribing to a mechanical paper that "they have worked at their business for twenty years and didn't need advice along mechanical lines."

This view is a very narrow one to take. The technical paper does not essay to show a man how to run his plant, but by telling what others are doing, giving news of the mechanical world, descriptions of new machinery, the opinions of other mechanical men, it undoubtedly provides a ready means of improving the knowledge in connection with the conduct of and work in the shop.

No matter how extensive a man's experience may be, he can still learn something from others and the technical paper serves as a means for this interchange of ideas. The fact that a man values his opinions so highly, should naturally lead him to place some value on the experience of others.

DEVELOPMENTS IN MACHINERY

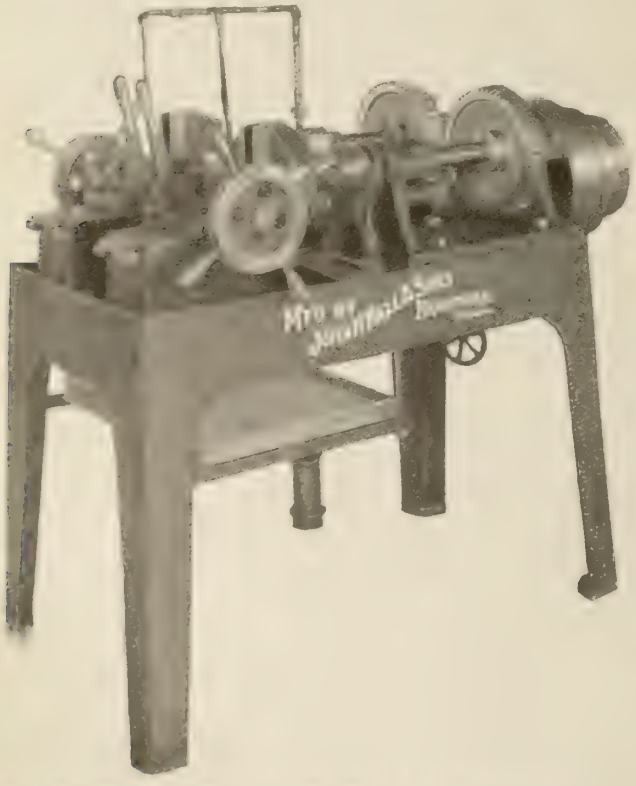
New Machinery for Machine Shop, Foundry, Pattern Shop, Planing Mill; New Engines, Boilers, Electrical Machinery, Transmission Devices.

PIPE THREADING MACHINE.

The new double head rapid nipple and pipe threading machine shown in the illustration has a capacity of $\frac{1}{8}$ to $\frac{3}{4}$ inch. inclusive. It reams and threads at one operation, pipes of any length from a nipple up, being quickly threaded on this machine.

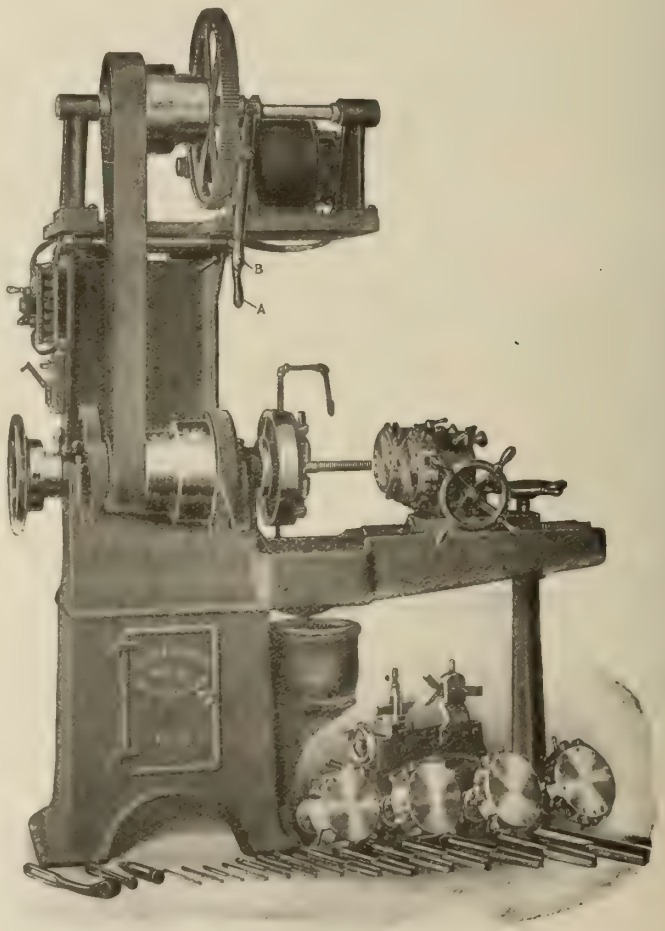
It is fitted with the Hall improved die head. The dies are easily made and permit being recut often. Rotary oil pump and drip pans form part of the equipment.

This machine is manufactured by John H. Hall and Sons, Brantford.



BOLT CUTTER AND NUT TAPPER.

The illustration shows a new motor driven machine made by the Wiley & Russell Mfg. Co., Greenfield, Mass. The machine proper is their standard combination opening die machine, equipped with their well-known patented "Quick Change" opening dies. Electric motor drive is attached to this standard machine. It can be used for nut-tapping, pipe-threading, cutting off, etc.



The arrangement is as follows: It consists of a bracket fitted and bolted to the bed on which the motor shelf is secured. This shelf is hinged at back and has finished projecting lugs which rest on cam shaft operated by lever A. By this sufficient tension can be kept on belt at all times and belt can be slackened off when desired to shift it from one step to another on cone pulley. After belt is tightened the cam shaft is locked with a binder.

The lever B, in front of motor controls the clutch in the large spur gear, so that the bolt-cutter can be stopped independently of the motor. The motor is constant speed and back geared and is fitted with a rawhide driving pinion. Motors can be furnished for direct or alternating current, reversing or non-reversing.

The arrangement is strongly and carefully fitted and machine is guaranteed to cut bolts and pipe to 2 inch diameter. A 2 h.p. motor is used. The weight complete is 2,300 lbs.

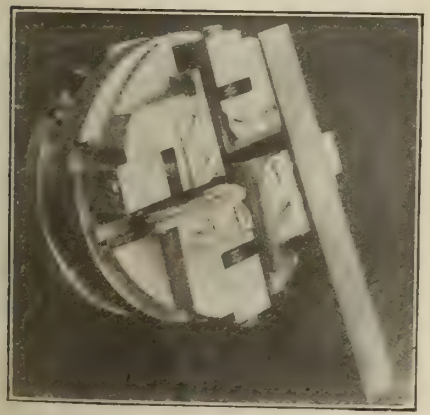
Pipe-Threading Machine, John H. Hall & Sons, Brantford

Bolt Cutter and Nut Tapper, Wiley & Russell Mfg. Co., Greenfield, Mass.

SOLID ADJUSTABLE DIE HEAD.

Landis Machine Co., Waynesboro, Pa., has recently brought out a new type of die head known as a "Solid Adjustable Die Head." The purpose of this die head, is to take the place of the solid dies now used on any of the screw machines and other types of machines wherein the work is backed out of the die after the thread is out.

The die head is illustrated herewith showing the 1 inch standard size which has a range from $\frac{1}{4}$ inch to 1 inch. It embodies the use of the high speed free cutting Landis die, with a very wide adjustment. The dies are adjusted to and from the centre on radial lines for different sizes and are held rigidly in their seats.



The die head is held in the turret of any ordinary screw machine and trips off by retarding the forward movement of the carriage. This die head will also be made without the tripping device for special requirements. The tripping arrangement is so set that when the desired length of thread is cut, the die head will trip and revolve with the work until the machine has time to reverse.

By using this die very high cutting speeds are readily acquired, equal to the turning and drilling speeds on the other operations of the screw machine, so that the speeds need not be reduced in the threading operation for the accommodation of the die as is the case with the solid dies.

Chasers can at all times be ground to suit the material to be cut; any amount of rake can be given that is necessary, thereby insuring the best possible cutting condition and securing ideal results.

The dies are made from high speed steel and can be ground and reground many times, thus giving a life many times greater than any other solid die, besides never requiring to be annealed, hobbed or retempered, and are readily adjustable to take up wear in addition to the adjustment for different diameters.

One set of chasers can readily be set above or below their rated diameter. For instance, ½ inch (13 thread) can be set to cut 1 inch diameter when de-

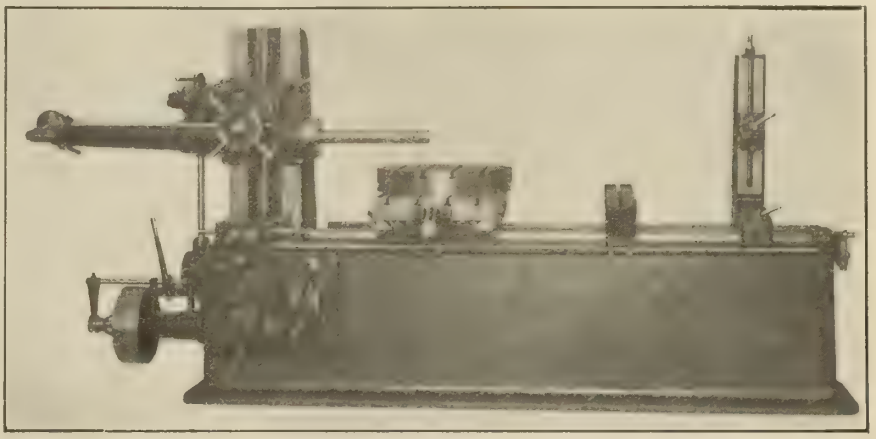
Solid Adjustable Die Head, Landis Machine Co., Waynesboro, Pa.

sired, or they can also be set to cut 1¼ inch diameter. The angle in the thread, however, will not be quite ideal, but all that is required for ordinary screw machine work. With other types of die heads a special set of chasers is required each time you wish to cut other than standard pitches. With this head any diameter within the range of the head can be cut with one set of dies so long as the pitch is the same. In very special cases where absolutely correct pitch is required, it would be advisable to use special holders so as to set the chasers on the exact angle to correspond with the angle of the thread. Ordinarily this is not required.

These heads can be supplied in standard sizes with shanks suitable for holders in ordinary screw machines. The ½ inch head is 2¾ inches in diameter, capable of cutting a thread of 1½ inches long. The 1 inch head is 4⅝ inches in diameter, capable of cutting a thread 2½ inches long. Other sizes with special shanks will be made to order.

The dies will regularly be made from high speed steel. In no other type of die can high speed steel be used to the same advantage as can be used in this die, as will be readily apparent on the face of same.

This head is manufactured by the Landis Machine Company, Waynesboro, Pa.



BORING, MILLING AND DRILLING MACHINE.

The machine shown in the accompanying cut is a horizontal boring, milling and drilling machine with tapping attachment and vertical feed.

The spindle runs in solid taper bronze bearings with adjustment for wear, and has a face-plate to receive large milling cutters, etc., for heavy work; it revolves in right or left hand directions and can be started, stopped or reversed instantly, this being convenient for facing, tapping, milling and other operations. The spindle and back gear drive is located between the spindle bearings, bringing the power direct to the work. The lever for operating back gear and the lever for reversing spindle are conveniently located on the spindle head, and they can be engaged or disengaged while the machine is running.

The spindle bar which passes through the spindle, is of unannealed crucible steel, 2½ inches in diameter, has 22-inch traverse, and is fitted with a No. 5 Morse taper. It has power feed in either direction; can be securely clamped for face milling purposes and is operated from the pilot wheel for both hand feed and quick traverse by means of a clutch.

The outer support for boring bar can be clamped securely to the bed, and is readily removed for overhanging work. The spindle head and outer support for boring bar are aligned by means of scale and vernier reading .001. The scales read 1-64-inch and 1-100-inch direct.

Boring, Milling and Drilling Machine, Cleveland Machine Tool Works, Cleveland.

There are 16 head, platen and bar feeds, 8 in number for each position of spindle back gear, are positive geared, and arranged in geometrical progression from .005 to .3-inch per revolution of spindle. All feeds are reversible. All changes of speed can be made while the machine is running.

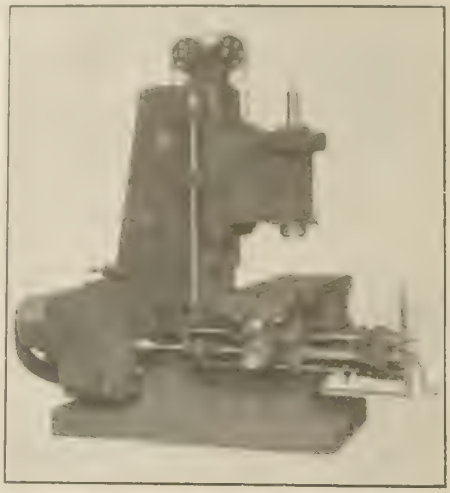
The machine is made by the Cleveland Machine Tool Works, Ohio.

VERTICAL MILLING MACHINE.

The half-tone shows a new vertical milling machine recently brought out by the Rockford Machine Tool Co., Rockford, Ill. It is adapted to modern manufacturing methods and the production of duplicate parts. The machine is a radical departure from the old precedent, the adjustable knee, which is in common use. The builders claim all the advantages of the adjustable knee with the elimination of their undesirable features.

The column and the horizontal slide for the saddle are made in one casting. By this construction, the table is not adjustable vertically, the top of table being 30 inches from the floor, the same height as a planer platen which is most convenient for the operator in handling castings or other parts being machined. The head bearing on column is fully as large as the bearing to the knee on a machine of corresponding size while the weight of the head is much less and counter-balanced, relieving the bearing of over-hang and uneven strains which rapidly destroy their accuracy.

The general dimensions of the mach-



ine are as follows—Distance from centre of spindle to column 15 inches, total length of table 56 inches, working surface of table 14½x48 inches, feet to tables 32 inches, maximum distance of table to spindle 21 inches, minimum distance of table to spindle 5 inches, the head has a vertical movement of 21 inches, and a bearing on the column 19 inches wide by 25½ inches long, the spindle is 4 inches in diameter at taper by 5 inches at upper end. It has an adjustment of 6 inches by means of sleeve and worm gear. There are twelve speeds to the spindle, nine back geared and three [illegible] open belt speeds for small cutters with twelve changes of feeds.

The drive is through a three-step cone pulley, diameters of which are 12, 15½ and 19 inches for 4 inch belt. The speed of countershaft is 390 r.p.m. Three speeds for each step of the cone are instantly obtained through the back gearing by the manipulation of a vertical lever on the side of the machine. The two levers are interlocking, preventing any two conflicting combinations of gears being engaged at the same time. By placing the vertical lever in its neutral position, the sliding gears are all locked out of mesh, then by moving the lower of the two levers to the right, the clutch is engaged with its mate which is out on the end of the shaft carrying the cone pulley and the three-high speeds obtained direct from the cone pulley to the bevel gears on the vertical shaft. Twelve speeds to the spindle are thus obtained which are 13, 16.6, 21.4, 27.4, 35.2, 45, 57.8, 74, 98.3, 121.6, 156 and 200 r.p.m.

The feed is driven by spur gear from the back gear shaft. The clutch for engaging and reversing the feeds is placed on the upper shaft which is the highest speeded shaft in the box. The lever for operating the clutch is conveniently placed in front of the machine. The power from the clutch shaft is transmitted through the slip gears at the end of the machine. Two pairs of these gears are used which are reversible, giving four changes. Three changes for each position of the slip gears are obtained by the sliding gears on the lower shaft which are operated by the lever on the front of the feed box. The feeds twelve in number range from ¾ to 17 inches per minute can be instantly applied to the table, the cross movement of the saddle, also to the head.

The power quick adjustment is a new and valuable time saving device. It is claimed by the builders that actual test of a machine so equipped showed a substantial gain in the production. A lever on the machine reversing the table moved by power. The power is supplied to the reversible clutch by spur gearing direct from the cone shaft. Transmission from clutch shaft is through the angle shaft equipped with universal joints to the feed train in front of the machine.

The operating lever is conveniently placed in front of the machine on the

Vertical Milling Machine, Rockford Machine Tool Co., Rockford, Ill.

right hand side. This is also interlocking, making it impossible for the feed works and the quick return to be engaged at the same time. The device is very simple and its operation is as follows:—The lever is pivoted with lower projection, engaging a rod passing through the shaft which is connected to a sliding collar by key through a slot in the shaft. A shaft passing through the column is connected by yokes at each side to the sliding collar and the jaw clutch on the feed shaft. An outward movement of the operating lever disengages the clutch on the feed shaft and the lever is free to be moved to the right and left, pass the projection on bearing casting, engaging the reversible clutch and applying power for the quick adjustment mechanism. On duplicate parts with an operator constantly on the machine, all movements can be controlled by this one lever, as it will be seen that by pressing the lever toward the machine, the feed is again engaged. However, this in no way interferes with the operation and use of the automatic stops to the longitudinal and cross movements. All slides are fitted with adjustable taper gibs, adjustable endwise to compensate for wear. The saddle slide is double gibbed, having a taper gib on the inside of right hand bearing, insuring perfect alignment when feeding under heavy cuts. All movements of the table, saddle, head and sleeve are provided with graduated collars, reading in .001. All shaft bearings are provided with wool felt oil retainers. A very efficient means is provided for oiling the driving shafts and feed box. Each bearing is connected by a soft brass tubes 5-16 inches in diameter which are brought up to a convenient location and grouped together in an oil cup, with hinged cover.

DOUBLE VERTICAL MILLING MACHINE.

The double vertical milling machine shown in the illustration was built by the Newton Machine Tool Co., Philadelphia. The spindle is 6⅝ ins. in diameter fitted with a No. 7 Morse taper. The construction permits of having only one feed at a time, but sufficient change gears are furnished to give feeds of .1211 in., .2071 in., .285 in., .0892 in., .0554 in., and .0357 in. per revolution of spindle. The feed motion is clutch and the drive is taken from the spur gear mounted beside the driving worm wheel.

The machine has a minimum capacity for cutters 25¼ inches in length and for cutters to a maximum length of 39¼ inches and up to 13 inches in diameter. The minimum distance from the work support to the centre of the spindle is 10½ inches and the maximum distance is 8 ft. 4½ inches. Reverse motion to the fast vertical elevation of the saddle is obtained through a double train of bevel gears engaged by a Carlyle-Johnson friction clutch.

The machine is driven by a 20 h.p. General Electric type DLC No. 2 motor,

Double Vertical Milling Machine, Newton Machine Tool Works, Philadelphia.

having a speed of 450 to 1,350 r.p.m. The motion is transmitted from the motor through a "quride" gear to the large driving spur gear mounted on the horizontal shaft on the side of the upright on which is also mounted a bevel gear driving the vertical spline shaft. The bevel gear on the vertical spline shaft is mounted above the bevel pinion. The stresses are thus counteracted and the thrust on the vertical spline shaft bearing is minimized.

POWER GENERATION AND APPLICATION

For Manufacturers. Cost and Efficiency Articles Rather Than Technical.
Steam Power Plants ; Hydro Electric Development ; Producer Gas, Etc.

BELTS AND BELT DRIVES.*

By A. E. B.

THIS concluding article on "Belts and Belt Drives," will treat of the influence of pulleys on belts, the installation of belting, the flapping of belts, the care and use of belting and belt joints.

Influence of Pulleys on Belts.

The outer face of a belt travels faster than the inner, causing compression of the latter and extension or stretching of the former. This process has a naturally injurious effect on the substance and life of the belt and should be miminized to the fullest extent possible, by using large diameter pulleys, those especially with little crown. Centrifugal force as is well known tends to raise the belt from the pulley face with the result that only the centre of belt width makes contact, thereby aggravating the ill effects

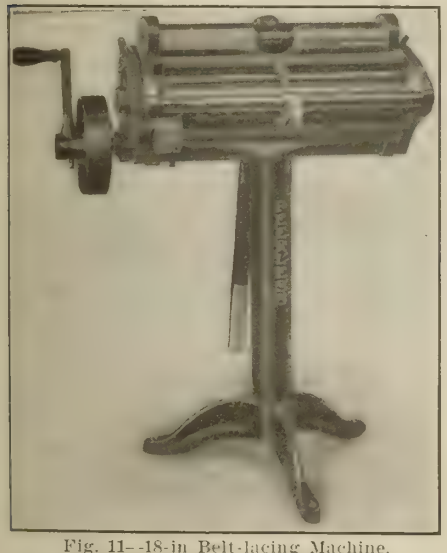


Fig. 11—18-in Belt-lacing Machine.

of tension and compression by a decreased surface.

Pulleys less than 12 inch and 18 inch diameter should be avoided, with single and double belts respectively. Crown pulleys of less diameter than the width of the belt for single belts and of less diameter than one and one-half times the width of double belts should also be avoided. The foregoing remarks apply more particularly to horizontal and flat angle shaft drives.

Horizintal shaft pulleys should have about $\frac{1}{8}$-inch per foot crown, while those on a vertical shaft should have about twice that amount. Flange pulleys chew the belt edges and should be side-tracked in favor of wider and extra crown-faced types. Fast and loose pulleys have also a tendency to distroy the edges of the belt due to the shifting operation.

To obtain a greater amount of power from belts, the pulleys may be leather sheathed, an arrangement admitting of a slack belt and a corresponding increase of durability.

Installation of Belting

In applying new belts, care should be taken that the proper side goes next to the pulley. Belts have what is known as a flesh face and a hair face, the former of which to the uninitiated might suggest itself as the driving face. This is not so however, for the reason that the flesh face being tougher, is better able to stand the stretching already referred to, and the hair side, which is predisposed to cracking, wears better under compression.

The top end of splices connecting the laps should point in the running direction of the belt. Pulleys should be somewhat wider than the width of belt necessary.

Horizontal belts and angle drives up to 45 degrees from the horizontal plane, should have a sag of about $\frac{1}{8}$-inch per foot, and the underside be the driver.

Vertical belts should be pulled tight to ensure grip on the lower pulley.

To connect two horizontal shafts running at right angles to each other by a $\frac{1}{4}$ twist belt, set the pulleys so that a plumb line from centre of face of upper pulley on side where belt leaves it, will strike centre of face of lower pulley also on side where belt leaves it.

Shafting and machinery should be so arranged that belts will run from the former to the latter in opposite directions in order to equalize the strain and pull on the bearings.

Tightening or guide pulleys are applied to the slack side of belts and located nearest the smaller diameter pulley.

Increase of belt width should mean a corresponding increase in thickness, and it is probably true that a thick and narrow belt is more durable and works rather more satisfactorily than does a wide and thin belt. This, of course, has regard to the fact that a certain well defined ratio of thickness to width must exist to ensure stability.

Flapping of Belts.

Flapping of belts is due to a variety of causes, to which the following are among the chief contributors ; the ends of the belt at the joint not being perfectly square, pulleys out of line and set at an excessive distance between centres, high velocity running, which tends to trapping of the air between belt and pulley, thereby diminishing the adhesive contact and the more so if the sag allowed exceeds that already stated under installation.

Sudden and often occurring change of engine speed due to heavy intermittent machine load, invariably causes flapping of belt, and is most generally only capable of cure by increase of flywheel weight, or by the substitution of a flywheel driving pulley for that in use.

The following pulley centres for given belt widths are suggested as a maximum to provide against flapping from this cause. Belts 4 inches and under, 15 feet centres ; belts 4 inches to 12 inches, 20 feet centres ; belts 12 inches to 18 inches, 25 feet centres ; belts over 18 inches, 30 feet centres.

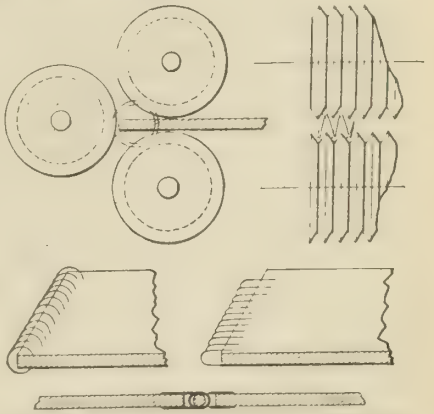

Fig. 12 Details of Belt-lacing Machine.

Trapping of the air may be counteracted by perforating the pulley rim or the belt.

Care and Use of Belting.

Leather belts should be well protected against water and other moisture, by using a waterproof leather dressing. Belts made of coarse loose fibred leather will give best service in dry and warm places. For damp or moist conditions the very finest and firmest leather should be used.

Oil should not be allowed to drip on to belts as it destroys the leather. Leather belting may not safely be constantly used above 110 degrees Fahrenheit.

Belt dressing should only be used as a preservative when the belt inclines to

*Part II. of the second article of the series on Power Transmission Equipment, Operation and Efficiency Subjects.

get dry, and should not be applied to secure unnatural adhesion.

Belt Joints.

It is preferable to joint the ends of a belt by splicing and cementing as it ensures against irregularity of running and consequent jar. Splicings of full width, V-shape and stepped are used on double, triple and quadruple belts respectively For double belts up to 10 inches wide the splice may be 10 inches long and for widths in excess of these the splice may be the same length as the belt width.

Laced belts should have the lace holes punched with an oval punch, whose longer axis is parallel to the belt lengthways. Lacing should not be crossed on the driving face of the belt.

With all forms of belt fasteners care should be taken that their surfaces on driving face of belt are sunk below that face. In our February article various forms of belt fasteners were illustrated and in this, details of a belt lacing machine are described and illustrated. Fig. 11 represents the complete machine equipped for hand or power operation and for use on an 18-inch belt. Fig. 12 shows the leading details which consist of 3 corrugated rolls, operated by a crank, between which is inserted a spiral needle. By revolving the crank the needle is carried through the ends of the belt and makes small perforations into which the coiled wire lacing is afterwards threaded by a similar process to that of perforating by the needle. The coils are afterwards flattened and forced well into the belt and are coupled together at the ends by means of raw hide pins, twine or other material suitable. The rolls and gears are made of the best hardened steel, and all parts are interchangeable.

Fig. 13 represents a leather belt 2½ inches wide laced by the Peerless belt lacing machine, which joint stood a tensile strain of 4,000 pounds without breaking or pulling apart.

Fig. 14 is a descriptive sketch comparison of hand and machine belt lacing, comment being needless.

Conclusions.

As a result of modern experimental work on power transmission by leather belting, much light has been thrown on the subject, with the result that possibly its future treatment will require revision. It appears proved that the greatest allowable belt tension is not constant, neither is the belt velocity even with pulleys revolving at constant speed.

The efficiency of a belt has been shown to be just as high as a good gear transmission, the loss in over-all belt efficiency being largely due to bearing friction, showing that the looked-for improvement should come from that quarter in the shape of ball or roller bearings equipment.

HANDLING ORE WITH ELECTRIC MAGNETS.

Magnetic iron ore is picked from the ground and loaded on cars for the crushers with electro-magnets at the Moose Mountain Mine, Ont. The ore is blasted from the side of the hill. At the bottom of the hill an electro-magnet connected to a crane loads it on the cars and at the same time leaves behind the rock and non-magnetic material.

An Electro Magnet Handling Plates.

The electro-magnet handles 1200 pounds of pig iron at a load and about 800 pounds of iron ore. The economy of the electro-magnet is self-evident. For some time buckets were used but had to be replaced very often at considerable cost. Then too, by the latter method the rock and other non-magnetic materials were gathered up and sent to the crushers. The electro-magnet now effects a saving by leaving these behind.

HOT SHOT.

In announcing their usual Christmas "dividend" to employes, based on 10 per cent. of each employe's yearly earnings, the Crane Co. recently denounced, in no uncertain terms, the practice pursued by some corporations of trying to induce their workmen to become stockholders. We quote their remarks verbatim: "We do not know of a more contemptible, low-down, cold-blooded fraud than the practice of some corporations who endeavor to tempt their workmen, in the disguise of a Christmas gift, to buy below the market price their stock, which has fluctuated all the way from five dollars to eighty dollars a share. If these people had a spark of decency they would never do anything of this sort but would advise their men to put their money into a savings bank where they would be sure that it was safe and would bring them in a small return. Another part of this contemptible scheme is to get their workmen to become stockholders and in that way have their friendship enlisted in their company's behalf and aid them in their unprincipled business methods."—Selected.

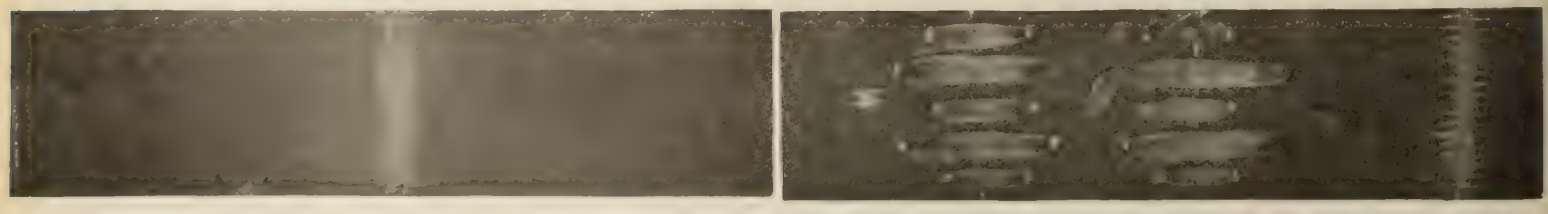

Fig. 14 Comparison of Hand and Machine-laced belts.

TOOL ROOM MANAGEMENT.

By G. C. K.

The efficiency of a machine shop can usually be quickly arrived at from an investigation of the tool room. In shops where efficiency and good workmanship is essential, there will be carefully arranged shelves of jigs, drills, reamers, bolts, dogs, chucks, clamps, wrenches, milling cutters, lathe tools, etc. The rooms are large, systematically arranged and in charge of a man who understands thoroughly tool work, tool grinding,, etc. There is also a system for taking care of the tools and other appliances. It is the intention of this article to suggest a system for shops where one is not at present in use.

There are some tools, bolts, blocks, etc., that are in constant use and tables have been devised so that these may be kept beside a machine and in a handy place for the operator. Certain milling cutters are kept at the milling machine, certain lathe or planer tools at a particular lathe or planer but there should be a central for all tools for general use and all expensive tools. In fact it is better when ALL small tools are kept in the tool room and accounted for by the one in charge. THE EFFICIENCY OF THE SHOP AND ITS PRODUCTIVE CAPACITY DEPENDS TO A LARGE EXTENT UPON THE CHARACTER AND COMPLETENESS OF THE EQUIPMENT STORED IN THE TOOL ROOM.

Situation.

The tool room should be placed as near the departments using the tools as possible, favoring those that, from the nature of their activities, demand most frequent intercourse with it.

Also, the tool room should be in a well-lighted situation. It is more likely to be kept clean and in order if well lighted. The light available should be sufficient for the man in charge to read readily the numbers of the jigs, etc. In addition numbers should be of sufficient size so that they may be easily deciphered. The tool room, for the same reason, should be provided with a good system of artificial lighting. THE QUESTION OF PROPER LIGHTING IS AN IMPORTANT ONE FOR HERE RESTS MUCH OF THE PROBLEM OF SAVING TIME WHEN TOOLS ARE REQUIRED.

Delivery of Tools.

In a small machine shop it is customary to let every man secure any tools he requires, but in larger ones telephone systems and messengers, pneumatic systems, dummy waiters, elevators, speaking tubes, etc., have been installed. Where there are a number of floors, the telephone, speaking tube, dummy waiters, elevators, etc., are of great service in reducing lost time and delays in the delivery of tools, jigs, etc., to a minimum. The National Cash Register Co., Toronto, use a dummy waiter for supplying stock, tools, etc., to other floors and it is found to be entirely satisfactory.

The factory telephone and the pneumatic system of delivery orders, tools, drawings, etc., will be the subject of two articles in succeeding issues of Canadian Machinery. The pneumatic system has been successfully applied to departmental stores and could be applied to factories with equal success and economy of time.

To assist in quick delivery the tool room attendant should not be hampered by closed cupboards. The open shelves are more convenient and are also cheaper to construct.

"Checking" Tools.

IT IS NECESSARY TO KNOW EXACTLY WHERE ALL THE TOOL JIGS ARE AT ANY TIME. Either they are in use in the shop or are in the tool room. In order that this condition may always exist a check system is found to be most satisfactory. The check should be of brass with a hole drilled in it for hanging on a hook provided on the side of the space from which the tool or jig is taken. A certain number of them on which is stamped the workman's number is given to the workman. In plants where this system is in operation it is customary to give the workman ten checks.

The following is the method of operation: A workman desiring a certain jig comes to the delivery window, states what he wants and hands over a check. The attendant hangs the check on the hook provided beside the space containing the jig, delivering the jig to the workman. When the jig is returned the check is handed back.

Classification.

EACH JIG, TOOL, ETC., IN THE TOOL ROOM SHOULD BE CLASSIFIED AND PLACED IN THE RACK SO THAT THE ATTENDANT CAN AT ONCE PROCURE IT. The general scheme of classification devised by Frederick W. Taylor, the author of the well-known volume on the "Art of Cutting Metals," was given in a recent issue of "Industrial Engineering," and is shown in the accompanying table. Subdivisions of it may be made where necessary:

Classification of Tools.

Class

A—MISCELLANEOUS TOOLS, not elsewhere classified.

B—BENDING TOOLS.—All tools for producing changes in shape by bending, folding, spinning, etc.

C—CLAMPS AND HOLDING DEVICES of all kinds, including bolts and screws.

D—DRILLING AND BORING TOOLS.—Tools that remove metal from the interior, such as drills, boring bars, cutters and all appliances relating to them, and lathe boring tools.

E—EDGE TOOLS.—Edge tools for working wood, and tools for working plastic materials, such as clay, molding sand, putty, etc.

F—HEATING TOOLS.—All kinds of tools used for heating, lighting, melting, molding, oil tempering, annealing, drying, cooking, etc.

H—HAMMERS AND ALL TOOLS that work by striking or being struck, such as sledges, tups, etc., chisels, sets, flatters, etc.

L—TRANSPORTATION TOOLS.—All tools used in moving materials from one place to another, such as buckets, boxes, etc., trucks, shovels, wheelbarrows, bogies, brooms, riggers' tools, slings, chains, etc.

M—MEASURING TOOLS.—All instruments of precision, weights, measures, gages, etc., electrical instruments, etc.

P—PARING TOOLS.—All tools that remove metal from the surface by cutting, except slotter and milling tools. (See class D for lathe boring tools.)

R—MILLING TOOLS.—All tools for milling or sawing metal.

S—SLICING TOOLS.—All parting tools and slotter tools.

T—TEMPLATES AND ALL INSTRUMENTS for duplicating work, including jigs and fixtures.

U—ABRADING TOOLS.—All tools for rubbing, scraping, filing, grinding, shearing, punching, breaking, etc.

W—WRENCHES AND ALL TOOLS used for causing rotation.

X—PAINTING TOOLS.—All tools used for covering a surface with an adhesive foreign material, and any for removing same.

According to the Taylor system a tool is designated by the first letters of the words describing the tools. Thus a lathe tool of class P, is 2PRBC, if it is a 2-inch cutting tool, round-nose, blunt and central with the tool or straight. These symbols are stamped on the tool and on the rack or drawer.

Where the Taylor system is used the racks are arranged according to the

classification, A, B, C, etc., and the letters designating the tools are prominently printed on the rack. The size of the tool room, the number of racks.

Conclusion.

A casual perusal of this classification may seem a little too elaborate for the average Canadian shop, but it will be found on a study of it that it may be easily applied. In a number of shops the forging and grinding of tools is entrusted to one man who thoroughly understands his business. Many shops too have shelves for tools and jigs and they are thrown together in a "hit and miss" fashion. It will be found to more than pay for itself if a convenient system is installed with a man in charge. The time saved in securing the jigs and tools will pay his wages and besides there will be a gain by avoiding duplication of tools or loss of them altogether.

Recently a new company purchased a large machine shop in Toronto where there was no system of looking after the tools and jigs. The first work was to gather up all the tools and rearrange the machinery. Racks were built and when the tools were classified it was found that there were two, three and even four tools of each kind, costing from $15 up. THE INVESTMENT IN TOOLS AND JIGS MUST HAVE BEEN ENORMOUS AND COULD HAVE BEEN AVOIDED BY A LITTLE INVESTIGATION ON THE PART OF THE MANAGEMENT AND THE INSTALLATION OF SOME SYSTEM FOR CARING FOR AND STORING THEM.

SYSTEM OF PURCHASING MACHINE TOOLS.

The sytem of purchasing machine tools, which has been adopted by the Chicago, Burlington & Quincy Railroad has invited a great deal of favorable comment among dealers and manufacturers. While it has been the custom of railroads and other large buyers to have committees which consider and recommend specifications or the purchase of machinery, the Burlington committee seems to have more power of initiative and has adopted a more progressive policy.

This committee made its appearance in the trade last fall in connection with purchases for new shops at Havelock, Neb. The committee visited all the Chicago dealers and made an extensive trip among the manufacturers soliciting demonstrations of machines and all the practical information that could be obtained from the experts of the manufacturers. The results were evidently satisfactory to the executive management of the Burlington system, as the committee is continuing its work by carrying through on the same plan occasional purchases for other shops of the system.

It seems that for about 20 years the Burlington has had an "Association of Operating Officers," which holds regular meetings, the chief object of the association being to promote efficiency and to secure general discussion by all the operating officers of proposed improvements. The Tool Committee is a regular committee of this association. It has no power to make purchases for the company, but it recommends all purchases of machine tools, and it usually specifies two or more competing machines before actual purhcase is authorized or bids invited.

This committee is composed of the most capable men for its work in the employ of the company. One member is the company's "superintendent of piecework," who travels over the system promoting piecework in all the company's shops, and at the same time keeping in touch with the progress of shop efficiency on other railroads and in commercial plants.

The committee has grown into an interesting piece of corporate machinery. It affords the executive mangement of the company a safe guide in appropriating money or authorizing improvements, and its successful record has given the progressive men who constitute the committee a degree of initiative that is unusual in railroad shop management. The individual shop foreman or superintendent often hesitates to recommend innovations or improvements, because a mistake in judgment would be a set back in his position with his company which would count more than credit for successful work. As a result of this peculiar phase of corporate psychology the foreman or superintendent is usually content to travel along in a rut, and when new machines are required he recommends those which have been used in the shop for 10 to 40 years, without profiting by the progress of the machine tool industry.

The shop payrolls of railroads in the United States amount to about $250,000,000 annually, while reports show the expendtiure of only $8,000,000 to $10,000,000 for shop equipment. There has been remarkable progress in the past 10 or 20 years in the efficiency of locomotives and train equipment, as well as in track and bridge construction, but the railroad shop has become a form of backwater in the stream of progress in railroad management.

The system adopted by the Chicago, Burlington & Quincy is apparently throwing light on this problem in railroad management. Recently the committee has disposed of a number of old machines, which have been replaced by new tools. Some that were found to have no commercial value in the market for used tools have been scrapped. These are unusual occurrences in the management of railroad shops. The committee has also shown a willingness to recommend the purchase of new tools that have never been used in railroad shops. When its members are out on an investigating trip and are entertained by a machine tool manufacturer or dealer they show a preference for water, while their strict attention to business has occasioned much comment.—Iron Age.

BOOK REVIEW.

Self-Taught Mechanical Drawing and Elementary Machine Design.—By F. L. Sylvester, M.E., with additions by Erik Oberg, associate editor of "Machinery." Published by the Norman W. Henley Publishing Co., 132 Nassau St., New York; size, 5x7½ ins.; pages, 333; illustrations, 218; bound in cloth; price, $2.

This book has been written to meet the demand for an elementary treatise on mechanical drawing, including the first principles of machine design, presented in such a way as to meet the needs of the student whose previous theoretical knowledge is limited. The author's aim has been to adapt the treatise to the requirements of the practical mechanic and young draftsman, and present the matter in as clear and concise a manner as possible. Practically all the important elements of machine design have been dealt with, and, besides, algebraic formulae have been explained, and the elements of trigonometry have been treated in a manner suited to the needs of practical men. In the arrangement of the material, the author has first devoted himself to mechanical drawing, because a thorough understanding of this greatly facilitates further study of mechanical subjects, then attention is given to the mathematics necessary for the solution of the problems in machine design, presented later, and to a practical introduction to theoretical mechanics and strength of materials; and, finally, the various elements entering in machine design, such as cams, gears, sprocket wheels, cone pulleys, bolts, screws, couplings, clutches, shafting, fly-wheels, etc., have been treated. The general arrangement makes possible a continuous course of study which is easily comprehended and assimilated even by students of limited previous training.

Graphite.—The July, 1910, issue of this house organ from the Joseph Dixon Crucible Co., Jersey City, N.J., contains several articles of interest to anyone interested in preservative paints, as this issue is devoted almost exclusively, to examples of what their paints will stand under very adverse conditions, photos being produced to verify their contentions. The paper is a well gotten up house organ.

FOUNDRY PRACTICE AND EQUIPMENT

Practical Articles for Canadian Foundrymen and Pattern Makers, and News of Foundrymen's and Allied Associations. Contributions Invited.

MOLDING PROPELLERS IN CORE.

By H. J. McCaslin.

AFTER reading Mr. Eastham's article appearing on page 60, Feb. issue Canadian Machinery,—molding heavy flywheels, which gives one a good opportunity of exercising his imagination as to how the cores are formed, etc., it occurred to me that it might be of interest to some of your readers to know that a similar method is employed in the production of propeller wheels when not exceeding 6 or 7 feet in diameter.

This practice when carefully carried out can be recommended in the making of test wheels where experimental data is desired; also in the production of metal patterns for standard size wheels, for it insures that the casting of all blades shall be as nearly alike as is practical to make them. Further by a slight change in the hub of blade pattern and core box the outfit may be used for a two or three as well as a four-blade wheel.

Nor is the method of molding confined to dry sand just because a core box is used, for by the introduction of a core arbor in the bottom or drag half of core for the handling of this part, a green sand mold may be formed if desired. However as the method of molding herewith illustrated is that of a dry sand steel mold, or what could be properly called a cored mold, our discussion will be along that line.

Fig. 1 shows a cast steel four-blade propeller of the throw back design, 6 ft. 6 in. diameter and 9 ft. pitch, with a chambered and tapered bore through hub.

In studying the arrangement of the core box as shown in Fig. 2, in which the cores are formed it will be noticed that the blade pattern is so placed in the box that the face or working side of blade is down.

This is done that this surface is more apt to be free from dirt or other impurities than if cast in the reverse position.

Attention is called to the hub when making this part of the pattern, for if the hub has an extreme swell or bulge at the centre difficulty may be experienced in its withdrawal from the sand.

For this reason a good practice is to slab or leave loose the interfering portions above and below that they may be drawn separately. Making the sides of the core box in sections as shown will greatly facilitate the core making— as this arrangement permits the tucking, ramming and rodding of the sand to be done from the side, in place of working from the top of core box if it be made entire.

The construction of the box is of little consequence if rigidity and stability is embodied therein, that the pattern may not become misplaced or rammed out of position.

To further guard against any misplacement which is very apt to occur in ramming, the patternmaker should get out and place in the hand of the coremaker such gauge or trial sticks as he deems necessary, and also indicate upon the pattern the point at which they are to be tried for correctness. Attaching a support at the tip of the blade as shown at A is good practice, it will prevent the pattern being rammed down, the depression left vacant thereby is easily filled up when finishing this surface.

Making the Drag Core.

The core-maker takes the job in hand and starts off by placing the lower section of core box upon a good level core plate, placing and securing the pattern in position and trying it for its correct location.

As this portion of the core supports the top or cope part during the drying and assembling of the mold, care should be taken that it is well rodded to hold the sand intact and that the lifting hooks are so placed as to ensure an even lift. With a good liberal silica facing against the pattern this part of the core is rammed up and a parting along the edge of pattern arranged.

But before applying the parting material (paper preferred) it is well to try in place the core arbor used in the cope half to see that it and the parting arrangement conform somewhat, as it is advisable to keep the arbor as close to the pattern and parting as possible.

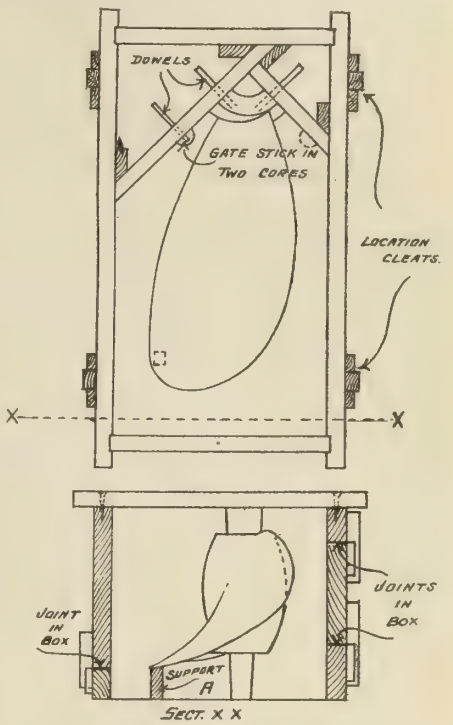

Fig. 2—Arrangement of Core Box.

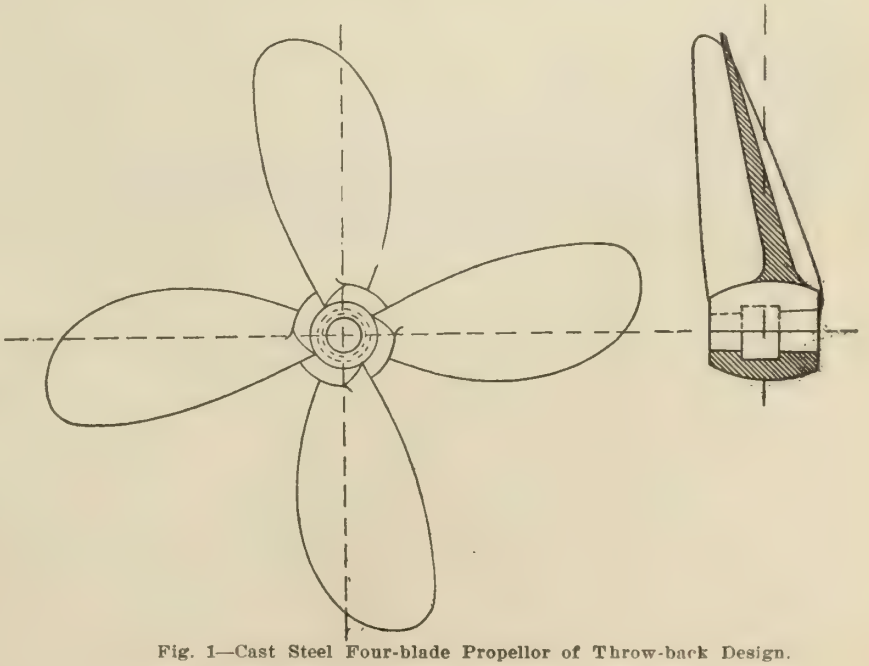

Fig. 1—Cast Steel Four-blade Propellor of Throw-back Design.

The Core Arbor.

The core arbor is cast, its formation consisting of a series of parallel ribs conforming somewhat to the twist of the blade at about the point they are to occupy when in place and connecting two parallel side ribs.

The outline of the core arbor is shown in dotted lines in one of the cores, Fig. 3.

The Core Arbor Pattern.

A pattern for the arbor can be easily and quickly made by setting up the core box and assuming about the position where the parting would be made.

Cut out the two side ribs to conform somewhat to this line and attach them to the side or ends of the box, in about the position they would occupy in the core.

Now cut out the cross ribs to conform to the twist of blade at the point they are to be placed and nail them to the side ribs. By giving the ribs plenty of draft no trouble should be experienced in drawing the pattern from the sand, but owing to its twisted form it cannot be made in an open sand mold.

Making the Cope Core.

With the parting arranged and prepared the silica facing is spread over the blade portion of pattern and tucked around hub, and the arbor placed in position, and blocked up the desired distance This part of the core is then proceeded with by ramming and tucking down and around the arbor and inserting rods where necessary to support the sand.

Provision must be made in two of the cores for the user heads as shown in Fig. 3 the runner which comes at the joint of two cores, and the vent or flow-off at the tip of each blade. This feature of mold is not exactly necessary but is often advisable to place them at such points.

At the completion of this part of the core the box is removed, the cope half of core lifted off and held suspended while the pattern is withdrawn and both parts of the core finished and prepared for drying.

The suspended or cope part is carefully and accurately placed back upon the drag half of core and the whole introduced into the oven and thoroughly dried.

Before assembling the cores they should be carefully inspected to see that no great degree of distortion has taken place in drying, and that the metal cavity is free from any dirt or sand.

In setting the cores together as shown in Fig. 3 upon a good level bed their spacing should be watched very close, for however good your cores may be you cannot depend upon their abutting surfaces bringing them to their correct position.

Make gauge sticks and try the cores at the centre as well as at the outlying points to assure a uniform spacing.

Cores will invariably swell in the drying process and a good practice to follow is to always allow a certain amount of clearance where the cores come together.

This amount of course would be determined or governed by the size of the abutting surfaces, in this case 3-32 of an inch on each surface would not be found in excess.

Fig. 3 illustrates the completed mold ready to receive the weights and the carrying up of the flow-offs. The aggregation of cores are of course firmly backed in with sand.

CONCRETE PATTERNS.

By K. Campbell.

Concrete patterns made of simple concrete and reinforced with steel have been advocated. One of the men who believes in them is Joseph Leon Gobeille, general manager of the Gobeille Pattern Co., Niagara Falls, N.Y. He made them in a small way and found they worked satisfactorily.

With pine wood patterns it was always an easy matter to figure the weight of the casting. This could not be done by putting the concrete pattern on the scales because no two cubic inches were

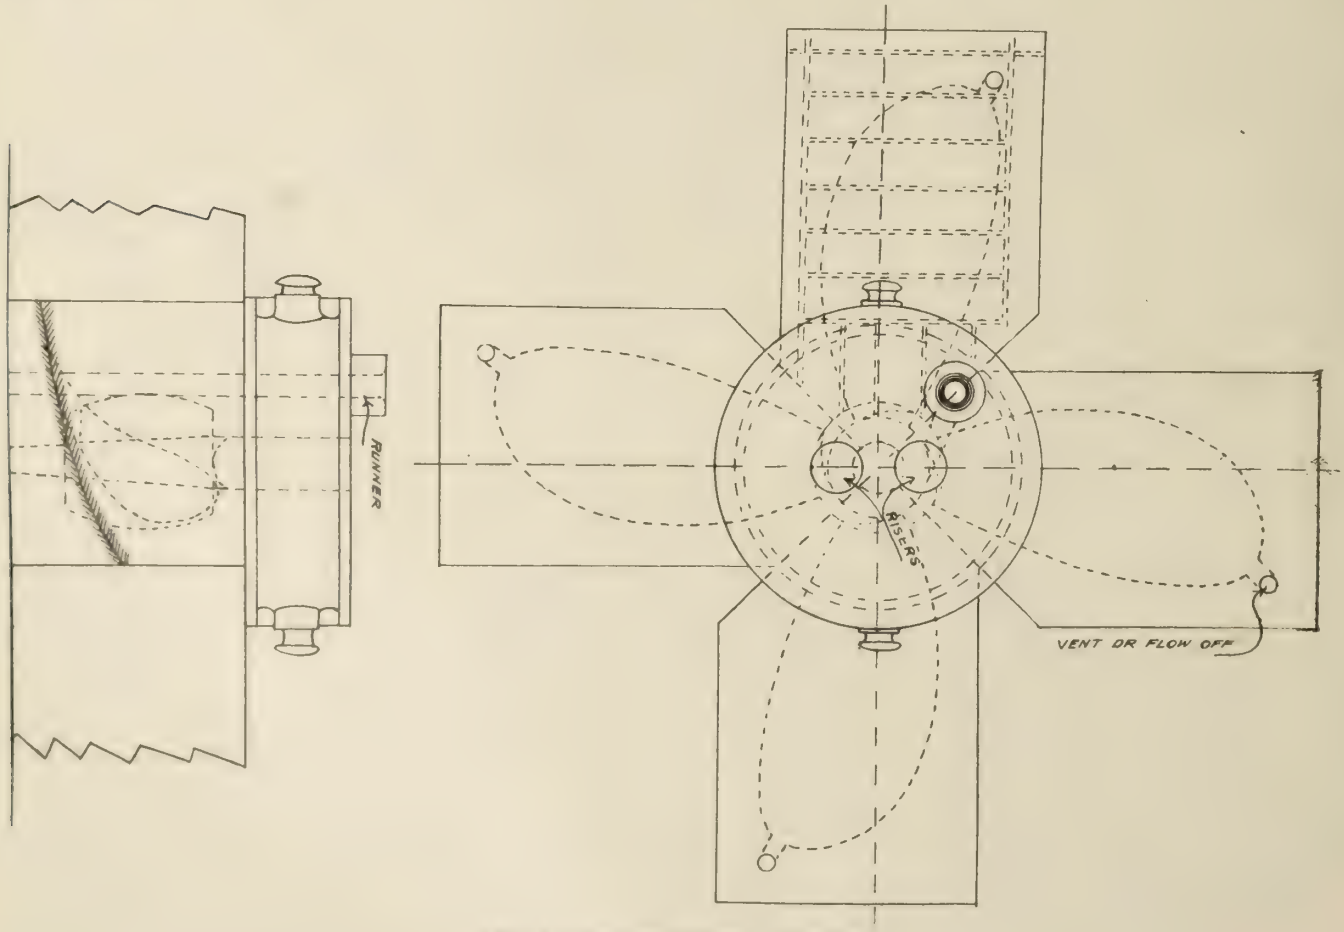

Fig. 3 Cores Set Together, Complete.

identical in weight. But another method of measurement was proposed and has been adopted by the Gobeille Pattern Co., which has given the accurate weight of the casting being obtained.

A square concrete tank was made of known superficial area. This was filled with water and a float with a vertical bar and an easy toggle was rigged up to a dial which was marked in pounds of iron. The decimal for the specific gravity of cast iron per cubic inch was known; the concrete pattern was submerged in the tank, the rising float actuating the pointer on the dial. The displacement of water in cubic inches was translated into pounds of iron on the dial without figuring and with no possibility of error.

PIECEWORK PATTERNMAKING.

By Shellac.

Patternmaking by piecework so far as the writer's observation and experience goes, is not a common practice in this particular trade; as a matter of fact I have only come across one firm who successfully operated the scheme.

The firm in question carried on a large marine engineering and boilermaking business, and made it a rule that the work of each shop department be done on a piecework basis.

It may be as well for me to say here that they had many years experience of the application of the system in other departments before applying it to patternmaking, it as a matter of fact being the last to come under the ban, if I might so speak.

Marine engine building has always appeared to me as rather a hard proposition to be tackled on piecework, and in the case of the firm in question, it was perhaps more so than ordinary. Their business practice was not in the tramp steamer line, where low piston speed, everything chunky and strong could be relied upon to gradually find its bearing without much risk and with the minimum of fitting to begin with. Conditions were rather just the reverse, being altogether high piston speed, quick revolution, high pressure, subject to severe test and inspection and likely to show up defects such as might be expected from a piecework system.

Suffice it to say, piecework was and is still a success in their experience, inclusive of patternmaking.

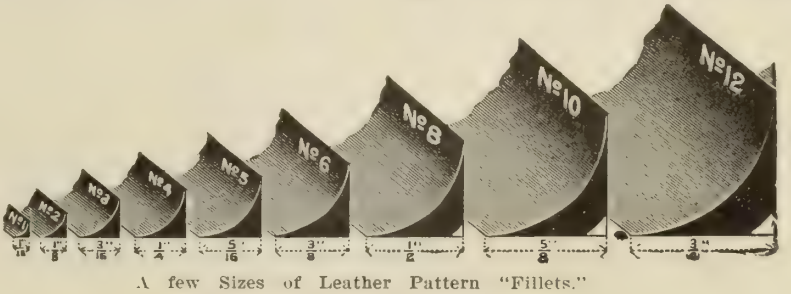
Marine work of the larger class especially lends itself I think fairly well to piecework patternmaking. Firms who make a speciality of a particular class of machinery usually find it to fluctuate between certain well defined limits of minimum and maximum size. This being so and the designs being in all cases similar, affords an attractive opportunity for the exercise of piecework.

The pattern staff consisted as a rule of from 30 to 36 men who worked in squads on the various jobs.

A similar system to that practiced in a large drawing office where checkers are employed, was adopted; there being two pattern checkers who were held responsible for measuring up the work when complete, and whose O.K. was the pass to foundry. Errors of construction, of course, were pointed out and put right by the constructors on their own time. The checkers were paid time for their work by the firm, being in no wise sharers of the squad contract money.

No question of the cheapest method of making the pattern, or of the proper construction for easy moulding and the securing of a reliable casting, required discussion. This as already pointed out was due to the work being standard type throughout.

The operation of this patternmaking piecework gave satisfaction all round, the individual members of each squad earning time and half as against ordinary time rates, and the employers gaining in better delivery and increased output.



Successful piecework patternmaking calls for first-class tradesmen, and while in some cases there would be no question of successful outcome, methinks its general adoption would bear hard on many second-raters.

LEATHER PATTERN "FILLETS."

By Beeswax.

Fillets are now used on all patterns except some very simple ones and are placed in all corners so that there may be no sudden changes in the direction of the metal. The leather fillet has almost altogether superseded beeswax and other material for the purpose.

Leather fillets can be bought from 1-16 inch up, the illustration showing a few of the sizes. They are pliable and are very quickly and easily applied.

A few Sizes of Leather Pattern "Fillets."

The following system should be followed to obtain best results from leather fillets:

(1) Cut to length and lay face downward on a board.

(2) Brush the glue over it easily. Use a good quality glue. For iron patterns use shellac varnish.

(3) Rub into place using a stick cut the shape of the fillet.

(4) Remove surplus glue with a sponge or rag dipped in hot water. The hot water in the outer glue pot may be used where an electric glue pot is not used. Care must be taken not to wet the pattern more than absolutely necessary. When glue is removed dry the parts that have been wet.

(5) When dry sandpaper in the usual way.

Do not use nails or tacks as they draw the fillet and make an uneven surface. Sometimes castings have their neat appearance spoiled by carelessness in inserting the fillet. In a number of cases that have come under observation this has been due to nailing the fillet in place.

MOTOR CAR BEARING METAL.

According to the "Foundry," a formula for a first-class tin babbitt, suitable for severe service, such as street car motor bearings, can be made as follows: Melt 435 pounds of Banca tin in a babbitt kettle and throw on the surface, finely powdered, soft coal. While the tin is melting place a clean crucible in the brass furnace and charge therein 25 pounds of copper; when red hot, add ¼-pound soda ash, a little salt and several handfuls of charcoal. Permit the copper to melt and to become hot, then add 1¼ pounds of bright tin plate, in small strips. Do not drop in all the tin plate at once, as when it becomes hot it will ball and weld together and will, therefore, be in such a condition that it can only be melted with difficulty. Add the tin-plate strips as gradually as possible, and stir between additions, so that all the iron is melted, and to insure this, it may be necessary to superheat the copper for a short time. Then add 6 ounces of sulphur, stir thoroughly, after which add 35 pounds of antimony, and when disssolved, withdraw the crucible and pour the contents into the melted tin, stirring as much as possible, meanwhile.

IS THIS TO BE YOUR HISTORY?

"Out of the chaos of mediocrity he came, up through the murk of the foundry, the clangor of the machine shop; up by brawn and brain to the Superintendent's chair."—Futrelle.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

FOUNDRY AND MACHINE SHOP.

EDMONTON, ALTA.—The Can. Nor. Ry. are preparing to spend $30,000 in extending their shops here. The plans call for an addition of six or eight locomotive stalls, and also additions to the shops.

VANCOUVER, B. C.—A well-known Montreal structural steel concern contemplate the erection of a branch steel and iron plant to supply the western trade. They have secured several options, chiefly on the Fraser river, near Port Mann.

GUELPH, ONT.—The Canada Gate Co. will locate here, and erect a plant to manufacture iron gates. They have secured temporary premises until their factory is completed.

HAMILTON—The Oliver Chilled Plow Works Co. will spend $600,000 here this spring enlarging their plant. They have taken out a $200,000 permit for buildings to be erected immediately.

MONTREAL—The Wilson Brothers Motor Co. has secured supplementary letters-patent, changing its name to the Motor Import Co. of Canada. The company is the Canadian representative of the celebrated Franklin air-cooled cars, and of the well-known Hudson, Thomas and Knox cars.

GODERICH, ONT.—The American Road Machine Co. of Canada, have made arrangements with the Hamilton Machinery Co. to sell their entire output, and will now give their undivided attention to their manufacturing business.

KINGSTON, ONT.—The North American Smelting Co. have purchased a site and will erect a lead smelter to treat the ore from their mines in Loughboro Township.

RIDGETOWN, ONT.—F. Eberle, of Morpeth, has taken over the machine agency lately conducted by W. Wilson.

PORT MANN, B. C.—The B. C. Steel Co. will establish a $10,000,000 plant here, and construction will begin this spring. French capital is behind the undertaking.

NEW WESTMINSTER, B. C.—The Drop Forge Manufacturing Co. will erect a tool factory here this spring and will employ 100 men. They will turn out all kinds of tools, including chisels, hammers, wrenches, etc. $125,000 is being invested as a starter.

OTTAWA, ONT.—The Board of Control has accepted the tender of Thomas Lawson & Co. for castings, $3.25 per 100 pounds.

CANORA, SASK.—A. Anderson and D. Gibney will commence the erection of a machine shop here early in the spring. A consignment of machinery is already on hand.

EDMONTON, ALTA.—Commencement has been made by the Edmonton Iron Works, on a contract covering five years, to manufacture 1,000 plows per year, from the Rountree patent. Special machinery for the manufacture of the plows is being installed.

NORTH BAY, ONT.—Fire damaged the C. P. R. car repair shops here recently, to the extent of $1,000.

EXETER, ONT.—Connor Bros. have acquired a site and will erect a factory here to carry on their machine business. It is their intention to go more extensively into the manufacture of air-cooled gasoline engines.

WINDSOR, ONT.—Windsor has secured two more important industries, the Canadian branch of the Maloney Electric Co., and the plant of the Canadian Winkley Co., a branch of a Detroit concern. The Maloney Co., which manufactures electrical machines, will build a $10,000 plant at once, while the Winkley Co., manufacturers of brass goods, will erect a $10,000 plant some time this year.

MONTREAL, QUE.—The Canada Ford Co., of Montreal has secured the contract for the supply of the electric cars required for the street railway system to be established by Regina as a municipal enterprise. The company is having the cars manufactured at the works of the Brush Co., in Loughborough, England. This is the first time an English street car has entered the western Canadian field, and it is probable that as an outcome the company will establish branch works in Montreal for supplying the Canadian market.

MONTREAL, QUE.—The "Belgo-Canadian Steel, Ltd." has been granted a charter, with an authorized capital of $5,500,000. The chief business will be general foundry work.

OTTAWA, ONT.—It is announced that a steel plant will be erected here by American and Canadian capitalists. They have purchased a site in the Bayswater district and will build in the spring.

FORT WILLIAM, ONT.—The Lumby-Stenhouse, Ltd., of this city, have opened a new plant, a foundry and machine shop, where anything in iron or brass castings can be made.

SACKVILLE, N. B.—The Charles Fawcett Manufacturing Co. contemplate making extensive improvements in their foundry plant this year.

BRANTFORD, ONT.—The gales here during the recent storms proved disastrous to several industries. The Ham & Nott Manufacturing Co. place their loss at $1,500. The company is putting up large additions to its works, consisting of a molding shop, machine shop, etc. The roof of the machine shop was partially demolished, while the molding shop is a wreck.

HESPELER, ONT.—Frank Roelofson has purchased the castings, tools, patterns, unfinished stock, etc., of the defunct Parkin Elevator Co.

REGINA, SASK.—The Regina Tractor Co. will erect a plant here, at a cost of $100,000.

TORONTO, ONT.—Mr. Robinson, of the Imperial Machine Co., of London, Eng., and New York, is here supervising the equipment of the Canadian factory and office for the manufacture of their patented machinery. The Toronto factory is getting equipped with a view of completely manufacturing every part of their machinery for the Canadian market with Canadian material and labor.

KINGSTON, ONT.—The Wilbur Iron Ore Co. have made arrangements for the construction of a large concentrating plant here. The cost of the plant will amount to between $75,000 and $100,000. The company will open up offices in the city on March 1st.

LONDON, ONT.—The directors of the London Street Railway have decided to put in a new steam plant.

NEW WESTMINSTER, B. C.—Work will soon be commenced on the plant of the Western Steel Corporation, on the Fraser river site. The corporation has purchased 300 cars of iron ore.

TILLSONBURG, ONT.—The Maple Leaf Harvest Tool Works are running to their full capacity at present, and cannot supply the market. The company intend doubling their capacity and largely extending their present plant.

TILLSONBURG, ONT.—The McCrea Foundry, purchased recently by the English firm of Taskell & Ormerod, is devoted almost exclusively now to the manufacture of gasoline engines. The firm hopes to soon rebuild the foundry, replacing the frame building with a brick structure, and otherwise improving and enlarging it.

WESTMINSTER, B. C.—Several Pacific coast steel and coal capitalists, representing the British Columbia Steel Co., are making application at Ottawa for a charter for the establishment of a $10,000,000 steel plant near here.

HALIFAX, N. S.—The I. C. R. has been asked to re-open the mechanical workshops here, closed some time ago.

MONTREAL, QUE.—The Joliette Steel and Iron Foundry Co. have opened offices at 371 St. James St. here. They will manufacture various classes of iron and steel castings. The president of the company is S. Vessot, of Joliette, and the vice-president, A. Baillot, of this city.

VICTORIA, B. C.—"Warden King, Ltd." has been granted an extra-provincial company license.

MONTREAL, QUE.—The corporation shops here were recently damaged to the extent of $5,000.

LONDON, ONT.—The London Foundry Co. intend erecting a large addition to their foundry here.

MONTREAL, QUE.—In view of the amount of large orders received, the Dominion Bridge Works are contemplating large additions to their plant here.

NEW WESTMINSTER, B. C.—A. Goldberg, of the Vancouver Junk Works, has purchased a site at Steel City, from the Western Steel Corporation, with two hundred feet of waterfrontage, immediately below the site of the proposed steel works. His plant is to be one of the many subsidiary companies to the steel works.

PORT MANN, B. C.—It is announced that the C. N. R. have decided to erect their B. C. car shops here. Several shipments of steel, supplies, etc., are already here.

MONTREAL—The Y. M. C. A. will erect a $300,000 building here on Drummond St.

ST. BONIFACE, MAN.—G. M. Ellis is contemplating the erection of a $1,250,000 automobile factory here. If erected, 1,400 horsepower will be required in connection with the machinery. Mr. Ellis has secured an option on 30 acres of land east of the Seine river, to be used as a site for the proposed building.

OTTAWA, ONT.—The Government has extended invitations to all the leading British and Canadian shipbuilders to inspect the plans and put in tenders for the ten new vessels of the Canadian navy, namely, four Bristols and six destroyers of the latest improved type. Following the rule of the Admiralty, the tenders are not being advertised, as details have to be kept secret, and only firms in whom the Department has confidence will have access thereto. It is stipulated that all the vessels must be built in Canada. The tenders, which must be in by April next, will be gone over by the experts in the Naval Department. In sending out these invitations, the Department has been strictly impartial, no distinction nor discrimination whatever being made between party firms.

CHATHAM—A new foundry is being opened up here for making grey iron, brass and aluminum castings, by the Ideal Foundry Co. Thos. Woods, of the Buhl Iron Co., Detroit, and Chas. Woods, of Chatham, are in charge of the foundry.

OTTAWA—A report states that the G. T. R. have extensive plans for the rebuilding of their shops here.

WESTMINSTER JCT., B. C.—It is reported that the C. P. R. intend establishing roundhouses, freight sheds and car shops in Coquitiam, near here. It is also understood that the C. P. R. plan to electrify their line between Westminster Junction and Vancouver and between the Junction and New Westminster.

PORT MANN, B. C.—As announced in a previous issue of Canadian Machinery, the C. N. R. shops will be erected here. About 500 men are clearing land for the C. N. R.

LINDSAY—The Sylvester Mfg. Co. has been re-organized. J. B. Tudhope, Orillia, will be associated with the new company.

ELECTRICAL NOTES.

CALGARY, ALTA.—Tenders will be received until March 22 for one 1,500 K.W. turbo generator set, with condenser, etc, one 100 K.W. exciter and switchboard, complete, three 1,000 K.V.A. single-phase transformers, 12,000 to 2,300 volts, with switching gear, etc. W. D. Spence, city clerk.

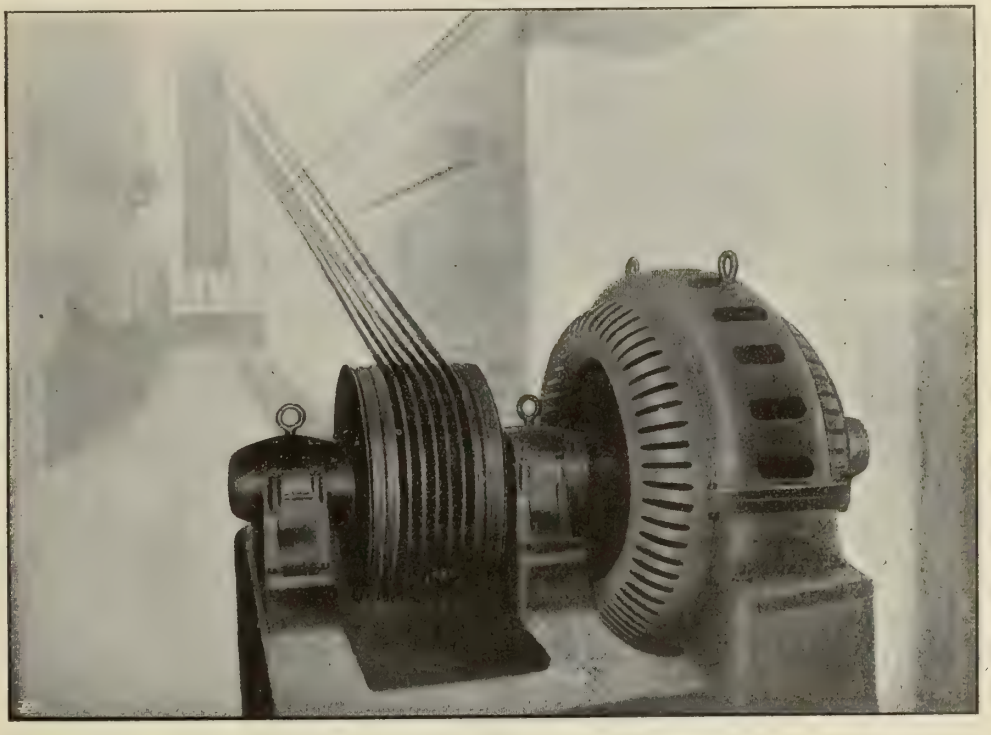
FREDERICTON, N.B.—Notice is given that at the next session of the legislature application will be made for the incorporation of a company to be called the St. Leonards Electric Co. The object of the company is to carry on a general lighting business in the parish of St. Leonards, Madawaska Co.

VICTORIA, B.C.—Certificates of incorporation have been issued to the "Albernie District Electric Light and Power Co.," "Consolidated Electric Heaters, Limited," "Cranbrook Garage Co." and the "Lillooet Power and Light Co."

TORONTO, ONT.—The "Electrical Maintenance & Repairs Co." have obtained a charter.

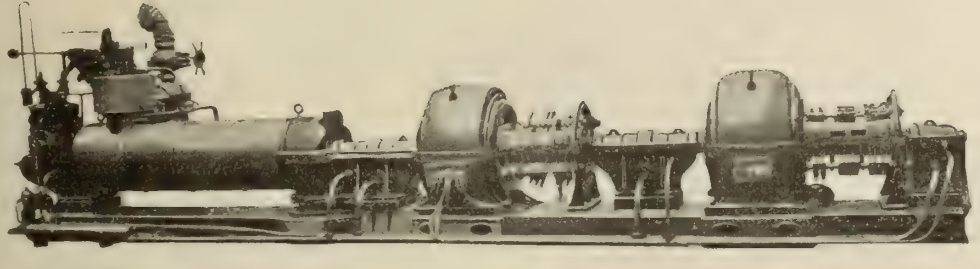
TORONTO, ONT.—The "Ross Motor Car Co." have obtained a charter.

MONTREAL, QUE.—The "Canada Electric Co." has been dissolved.



MERRITT, B.C.—The electric lighting plant here has been completed and has a capacity of 1,150 lights. Provision has been made for extensions.

PORT ARTHUR, ONT.—The Kaministiquia Power Co. have decided to double the capacity of their plant owing to an excessive increase in business.



PORCUPINE CITY, ONT.—The Symmes-Timmons Co. has a contract to develop 3,000 horsepower here. They are erecting dams and putting up power stations on the Mattagami river. Fifteen teams are now employed in drawing in machinery, wire and cement with other material for the works. It is expected that the contract will be finished by June 1.

CHURCH LANE. - - SOUTH BEND, IND.

The advertiser would like to know where you saw his advertisement—tell him.

MONTREAL, QUE.—According to recent estimates the St. Lawrence, as a whole has a capacity of ten million horsepower, and the Ottawa River, 2,375,000, most of which is at present undeveloped.

KINGSTON, ONT.—The municipal light plant made a net profit of $18,000 in 1910, the largest surplus in years. Electricity was produced at 1.61 cents per kilowatt hour, a reduction of a quarter of a cent over 1909. Gas was produced at 42 cents per 1,000 cubic feet. In 1909 it cost 47 cents.

HAMILTON, ONT.—The report of the Dominion Power and Transmission Co. showed a prosperous year. The assets of the company are $19,355,247, and it has to the credit of profit and loss $1,019,689.

MONTREAL, QUE.—Plans will be ready by the end of March for the new power house for the Saraguay Co. They include specifications for two steam turbines of 4,500 maximum h.p. capacity each, boilers and general equipment.

LONDON, ONT.—The C.P.R. are making improvements in their yards here. An up-to-date round house is being constructed in the east end yards. A large amount of the finest machinery will be installed and power will be obtained from the city.

ST. JOHN, N.B.—Ontario capitalists are behind a scheme to erect a power plant at the reversing falls of the St. John.

CALGARY,, ALTA.—The city will submit a by-law calling for an expenditure of $380,000 on electric light extensions, including the erection of substations for receiving hydro-electric power from the Calgary Power Co.

EDMONTON, ALTA.—Formal application has been made to the Dominion Government by the city of Edmonton for power rights on the Grand Rapids on the Athabasca River. Plans filed with the application show a maximum power if all the dams are built of 60,000 horsepower. Edmonton hopes to interest the Government in a hydro-electric scheme. If this is impossible the city hopes to be able to reserve rights until able to build the plant and distributing power itself.

RENFREW, ONT.—Engineers of the Hydro-Electric Commission have visited the upper lakes of the Bonnechere River looking for sites for dams for storage purposes. The town is expending $150,000 for power development.

OTTAWA, ONT.—It is estimated that the expense of developing and utilizing the Trent River powers by the Electric Power Co. will be a sum in the neighborhood of $15,000,000.

EDMONTON, ALTA.—The Diamond Motor Co., Calgary, capitalized at $10,000, has been incorporated.

WINNIPEG, MAN.—The Winnipeg Electric Railway Co. has let the contract for their new power plant to the Canadian General Electric Co. The plans call for a rated capacity of 12,000 horse power and a maximum capacity of 17,000 horse power, ready for delivery by August 1, next. The generator will be driven by Curtis turbines, and the equipment will be installed in four units of 3,000 kilowats each.

ST. BONIFACE, MAN.—The E. B. Reese Engineering Co. has secured the power contract here for a period of ten years, beginning Dec. 31, 1912. The price for power is to be $18 per h.p. up to 3,000 h.p. and over 3,000 h.p. and under 4,000 is to be reduced 25 cents per h.p. for all power used; and for every additional 1,000 h.p. used the price is to be reduced an additional 25 cents. After 15,000 h.p. is used the price is to be $15 per h.p.

New Companies.

MONTREAL, QUE.—Williams and Wilson, Limited, have been incorporated to do a general business in manufacturing, buying and selling machinery and machinists' supplies. A. R. Williams, merchant, Toronto; F. C. Wilson, merchant, W. A. Wilson, barrister, M. B. Bronstetter and E. Kingsland, salesmen, all of Montreal. Head office here.

ST. JOHN, N.B.—The St. George Pulp and Paper Co., of Hudson Falls, N.Y., capital $460,000, are applying for incorporation in New Brunswick.

TORONTO, ONT.—Standard Chemical Iron and Lumber Co., of Canada, Toronto, incorporated, capital, $6,000,000. Incorporators, J. Wood and T. W. Lawson, barristers, both of Toronto.

MONTREAL, QUE.—Belgo-Canadian Steel, Limited, Montreal, Que., incorporated, capital $550,000. Incorporators, E. Van Acker, importer; A. Menager, engineer; F. A. Beique, advocate, and L. J. Beique, all of Montreal.

HAMILTON—The Climax Good Roads Machinery Co., Hamilton, incorporated, capital $40,000. Incorporators, J. Robinson, manufacturer, W. J. Robinson, drug clerk, both of Hamilton, Ont.

WINNIPEG, MAN.—The Winnipeg Steel Granary and Culvert Co., capitalized at $100,000, has been incorporated to manufacture corrugated steel products, chiefly for railroads and municipalities. They will have a plant here and a branch at Regina. Incorporators, L. Crossen and P. Clarke, both of Cobourg, Ont.

MONTREAL, QUE.—The "Central Canada Iron and Steel Corporation," capitalized at $500,000, head office here, has been incorporated. They will carry on the business of iron masters, steel makers, steel converters, smelters, engineers, iron founders, etc., and deal in plant, machinery, implements, etc., and construct bridges, furnaces, saw mills, hydraulic works, electrical works, shops, etc. G. V. Cousins and O. B. MacCallum, barristers, S. T. Mains, accountant, P. F. Brown, secretary, W. R. Ford, clerk, all of Montreal.

BROCKVILLE, ONT.—The "Brockville Construction Co.," capital $100,000, has been incorporated here. This company will require machinery, tools, engines, boilers, plants, implements, patterns, rolling stock, etc.

OTTAWA, ONT.—The "Canadian Quarries and Construction Co." capitalized at $2,000,000, has been incorporated with head office here. They will carry on the business of engineers, foundrymen, machinists, tool-makers, boiler-makers, etc., etc. J. Black, broker, R. T. Mullin, barrister, both of Montreal; S. Bilsky, jeweller, G. C. Hurdman, lumberman and J. O. Carss, barrister, all of Ottawa.

OSHAWA, ONT.—The Matthew Guy Carriage & Automobile Co., of Oshawa, the outgrowth of the long-established carriage business of that name has been incorporated with $250,000 capital stock. It will produce a 30 horse-power touring car and a one-ton truck.

The Cushman Chuck Co.
Hartford, Conn., U.S.A.
Established 1862

WELLAND, ONT.—The water commission has secured a water power privilege on the east side of the canal and will build a large modern waterworks plant. A 3,000,000 gallon pump and an electric auxiliary power plant will be installed.

CALGARY, ALTA.—The city is submitting by-laws to the ratepayers calling for the following expenditures: incinerators, $120,000; asphalt plant, $20,000; conduit system, $60,000; waterworks extensions, $245,000; service connections, $40,000; electric light, $380,000; and fire station, $75,000. Total $940,000.

VANCOUVER, B.C.—The civic authorities have presented an application for water rights on Seymour Creek covering the establishment of a storage system on the stream which will enable the installation of supply mains capable of fully meeting the demands of the population of Great Vancouver in the years to come.

NORTH BAY, ONT.—A new electric pump will be installed at the waterworks in the near future.

VICTORIA, B.C.—Plans for the extension of the sewer system are being prepared by the engineer. The ratepayers will probably be called upon to authorize an expenditure of $250.000.

LONDON, ONT.—The Springbank pumping station will be equipped with electric machinery by the first week in March. There will be two pumps with a capacity of 3,000,000 gallons each. The synchronous motors will be of 250 h.p. capacity. The installation of the electrical machinery means that the steam plant at Springbank will be done away with.

CAMROSE, ALTA.—The municipality is installing a new waterworks and sewage system.

NORTH PORTAL, SASK.—The C.P.R. have decided to solve the water problem here; and during the coming summer will install a pumping plant to cost $50,000.

QUEBEC, QUE.—The city is making a strong bid for a big shipbuilding plant, one which is prepared to undertake the construction of the largest warships. Hugh Russel is acting for the company enquiring. He desires to establish yards here, so as to be able to tender for the new ships of the Canadian navy. It was decided to offer an exemption from taxes for 20 years, as well as a liberal bonus should the company locate here.

PRINCE RUPERT, B.C.—Surveys have been completed here with a view to forming plans for the proposed new waterworks.

SCOTSTOWN, QUE.—A by-law providing for a new sewerage and waterworks system will be submitted to the ratepayers on the 6th of March.

OTTAWA, ONT.—The waterworks committee has awarded the tenders for supplies for the year. It is estimated that about $5,000 worth of piping, castings, brass, oils, etc., will be required. The tenders accepted were: Cast iron pipes, A. W. Fleck, representing the Canada Iron Co., $11,583.40; special pipe castings, the Canada Iron Co., $2.70 per cwt.; hydrants, Chaudiere Machine Co., $38.50 each; oils and grease, Capital Warehouse Co., $390.50; valves, Chaudiere Machine Co., $1,148.15; lead pipe, McKinley & Northwood, $1,801.10; brass, Robt. Mitchell & Co., Montreal, $1,915.50.

WINNIPEG, MAN.—Prominent business men here are urging the city to instal a municipal gas plant. This is the result of the high present rate, namely $1.20 per thousand. The city will probably decide to do so, seeing that the electorate voted $700,000 for a gas plant in 1904.

TORONTO, ONT.—The city will, shortly, float a loan for one million dollars to meet the cost of installing the hydro-electric system. So far $700,000 has been spent upon the system within the city limits; this was secured by local loans. Two years ago the city secured authority to issue debentures for $2,750,000 for the installation of the system.

VANCOUVER, B.C.—The announcement is made that the $400,000, voted for the waterworks extension, is inadequate and another by-law will be submitted in the near future asking for $223,000.

VANCOUVER, B.C.—City Clerk McQueen is calling for tenders for the supply of brass goods for the waterworks department.

OTTAWA, ONT.—A by-law may be submitted to the people shortly to authorize the expenditure of $195,000 for waterworks purposes. For the completion of the work on the aqueduct $150,000 is needed and over $40,000 is required for water main extension on the Glebe.

Saw Mill and Planing Mill News.

NEW WESTMINSTER, B.C.—A local syndicate, said to be representing a company of English capitalists, have acquired a large site near here and intend erecting a saw mill to cost over $500,000 and employ several hundred men. Names of the purchasers are not obtainable.

DALHOUSIE, N.B.—Chappell Bros., of Sydney, N.S., will likely erect large saw and planing mills here. They are asking certain concessions and public opinion is in their favor.

LADNOR, B.C.—The saw mill of the Jervis Inlet Lumber Co. was destroyed by fire recently. Lass, $20,000. It was fully covered by insurance and will be rebuilt.

FREDERICTON, N.B.—H. Holland has added a third boiler to the equipment of the Robinson saw mill at Lower St. Mary's. He also added 84 feet to the mill chimney which was previously 80 feet high.

SOURIS, P.E.I.—B. Creamer's planing mill is burned out.

SUMMERSIDE, P.E.I.—The planing mill of M. F. Schurman & Co., here, was burned out.

WOODSTOCK, N.B.—J. A. Hayden's saw mill has been burned. No insurance. It will be rebuilt.

ST. JOHN, N.B.—P. Mackay has been appointed liquidator for the "Nepisiquit Lumber Co.," manufacturers of lumber and shingles.

NORTH VANCOUVER, B.C.—J. J. McDonald, who has for the past few years managed the Burrard Sash and Door factory, has sold out his interest in the business to Medcalfe & Suiter.

BOISSEVAIN, MAN.—The Rat Portage Lumber Co. have bought the T. Taylor Lumber Co., here, for $20,000 and are now in control.

TORONTO, ONT.—An order winding up the Belding Lumber Co., East Toronto, has been granted by Justice Sutherland. G. T. Clarkson is named interim liquidator, and a reference is directed to the Master in Ordinary. The company's nominal stock is $40,000. The assets are placed at $18,000, and the liabilities at $20,000.

SHERBROOKE, QUE.—C. F. Haseltine is putting in a fine new steam saw mill. He expects to have it in running order in March.

GALT, ONT.—P. W. Gardiner & Son have decided to erect two more additions to their planing mill plant here, one immediately to enlarge the glue room.

PITCOX, ALTA.—Walsh Bros. and Addy have purchased through Stewart Bros., at Penhold, a complete saw mill, planer, etc., and a 32 h.p. traction engine which they have installed nine miles west of here.

LETHBRIDGE, ALTA.—The Western Canada Lumber Co. have opened a yard at Medicin Hat and also at this place. They will erect here a large shed 100 x 60 feet.

VANCOUVER, B.C.—The Koksilah Lumber Co., of Vancouver Island, has been incorporated.

NEW WESTMINSTER, B.C.—R. H. Pogue, of the Royal City Planing Mills, this city, has invented a saw protector, to prevent workmen from injury. It is a metallic hood with a traveling shutter on each side, which drops to the surface of the board irrespective of its size or formation.

REVELSTOKE, B.C.—The Dominion Saw Mills Co. have begun operations on the building of their new office structure here. The building will be two and a half storeys and modern in every respect. It will be steam heated. The company expect to take posession by the end of May.

BEULAH, N.B.—M. Jones and E. Vanwart have purchased the Palmer saw mill at Tennants Cove, and have begun operations.

RAINY RIVER, ONT.—Seventy-five carloads of machinery for the mills of the Shevlin-Clark Co. have been ordered and a crew of men have started to build a spur into the company's property here from the main line of the C.N.R.

General Manufacturing.

VICTORIA, B.C.—The "Ideal Manufacturing Co." is among several extra-provincial companies registered.

WINNIPEG, MAN.—A factory for the manufacture of automobile tire covers and treads will be opened in Winnipeg on April 1 by the Tripie Tread Manufacturing Co.

PRESTON, ONT.—The Canada Buffalo Sled Co. will secure a factory here and manufacture boys' wagons and steerable sleighs. The firm is a combination of the Buffalo Sled Co. and Werlich Bros., of this place.

WINNIPEG, MAN.—The "Western Manufacturing Co." have been incorporated here, with a capital stock of $250,000. They will deal chiefly in lumber, timber, building, construction, etc. C. M. Boyton, R. T. Ferguson, H. Lillie, G. Murray and R. Siderfin, law clerks, all of this place.

ST. JOHN, N.B.—R. M. McCarty, of this city, is promoting a concern which proposes to establish a $500,000 cement industry here. They propose to erect a modern cement manufacturing plant with a capacity of 1,200 barrels per day.

TRENTON, ONT.—The Canadian Button Co., organized recently, will erect a factory here in the early spring. A carload of machinery has already arrived. A. A. Ullyot is general manager. At present the company is working in temporary premises here.

GANANOQUE, ONT.—Work at the Ontario Wheel Co. has been resumed, the new buildings having been completed and the machinery installed.

NEW WESTMINSTER, B.C.—The machinery for a large brickyard at Cloverdale has been assembled and the promoters of the new industry hope to be turning out brick early in April.

PETROLEA, ONT.—The Shuttleworth Co., Tile manufacturers, contemplate a large addition to their plant here.

FREDERICTON, N.B.—The Chestnut Canoe factory here will be greatly enlarged.

LINDSAY, ONT.—It is generally conceded that operations will be re-commenced in the Rider & Kitchener factory here. They will manufacture excelsior exclusively.

MONTREAL, QUE.—The "Cotton Prints Co." have acquired a site and will erect, in the early spring, a cotton converting works for bleaching and printing cotton fabrics. It is understood that the machinery is already ordered or at least its manufacture is being considered. The plant will be furnished with electric power and will be up-to-date in every particular.

MONTREAL, QUE.—The Western Manufacturing Co. are erecting a large factory at the corner of Duluth and Mitcheson St.

WELLAND, ONT.—As reported in last month's issue, the Canadian Automatic Transportation Co. will build a factory here, 150 x 50 feet. Sufficient stock has been sold to make the undertaking a certainty and ground will be broken in early spring.

TILLSONBURG, ONT.—The Canadian Cereal and Milling Co., which bought the Tillson Mills about a year ago, are improving and enlarging their plant. The output at present is about 1,200 barrels a day and about 50 men are employed.

TILLSONBURG, ONT.—The Borden Condenser intends extending its handsome buildings this spring to about twice the present capacity. It is understood that the extension will be about forty feet on the west side of the present factory and sixty feet on the east side.

EDMONTON, ALTA.—The Cardiff Collieries of Morinville are installing a new plant at the mines and increasing the output. They will spend $100,000 on the plant.

MOOSE JAW, SASK.—The Moose Jaw Blacksmith and Carriage Repair Co. is the name of a new local co-operative company recently formed here.

MITCHELL, ONT.—The Hill & Co. bridge works firm have closed a number of contracts for bridges and the outlook for the coming season is bright.

Building Notes.

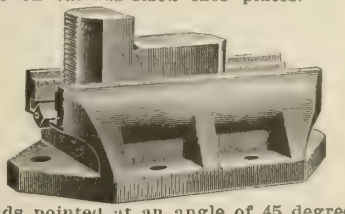
MONTREAL, QUE.—Holt-Renfrew Co. have purchased a site and will erect a large cold storage plant here. It will be a six or eight storey building equipped with the latest plant and machinery for the cold storage of furs, etc.

MONTREAL, QUE.—Henry Birks & Sons will, shortly, erect an office building 90x130 and several storeys high, on the corner of Union Ave. and Cathcart Street.

MONTREAL, QUE.—The Colonial Real Estate Co. will erect a ten storey sky scraper on St. Catherine St. The building will be of reinforced concrete faced with terra cotta.

MONTREAL, QUE.—The Homoeopathic Hospital on McGill College Avenue will be rebuilt this year at a cost of $100,000.

SASKATOON, SASK.—A. Bowerman is contemplating the erection of a $140,000 business block here. It will be of reinforced concrete, modern in every respect and fireproof.

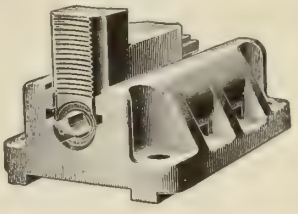


ST. JOHN, N.B.—The C.P.R. is planning to spend more than a million dollars on terminals here.

EDMONTON, ALTA.—The Pembina Coal Co. have set aside $1,000,000 for development purposes on their property near Entwistle.

PRINCE RUPERT, B.C.—The Pacific Coast Construction Co., of Victoria, has secured the contract for the depot of the Marine Department for a sum approximating $200,000.

Face Plate Jaws



New features include extra large screws, double thrust bearings and special methods of attaching, permitting their use on various-sized face plates.

Ends pointed at an angle of 45 degrees so that four jaws will fit close together at centre. Sizes 4-in. to 14-in.

Boring Mill Jaws

As in the face plate jaws, screws are larger than usual, thrust bearings are double and jaws are wider, heavier and better supported. Made in all steel or with grey iron base as desired.

JOSEPH DIXON CRUCIBLE COMPANY
JERSEY CITY, ... N.J., U.S.A.

Among other operations the work consists of erecting work shops, power house, etc.

MONTREAL, QUE.—The Dominion Express Co. will erect a ten-storey office block on St. James St. It will have a sub-basement given up to the machinery used in running the heating, ventilating and ice-making plants. W. S. Maxwell, of this city, is the architect.

GEORGETOWN.—The Georgetown Coating Paper Mills have erected a large plant which is now in operation. L. E. Fleck is manager.

STRATHCONA, ALTA.—Recent developments indicate that P. Burns & Co. will, no doubt, erect their $1,000,000 packing plant here.

WINNIPEG, MAN.—Gowans-Kent Western, Limited, are building a fine new eight-storey structure here on Market St. Carter-Halls-Aldinger Co., builders, have the contract.

WINNIPEG, MAN.—J. J. Hill announces that he will build a $1,000,000 depot here for his Great Northern, Northern Pacific and Midland Railway.

CALGARY, ALTA.—J. Walker will erect an eight storey business block here this spring. It will have two passenger elevators and plumbing, heating and ventilation of the most modern type. Cost, $175,000.

TORONTO, ONT.—It has been announced here that a big paper mill will be erected at Espanola at a cost of $1,000,000 by the Spanish River Pulp and Paper Co. Work will soon be started and it is planned to get it in operation by Oct. 1. The mill will have a capacity of 100 tons of paper daily, and the pulp will be supplied from the present pulp-making plant, which has a capacity of 125 tons daily. Tenders are now being called for the buildings, and the machinery has been ordered from firms in Canada and the United States. The whole paper plant will be under one roof and the building will be about 525 feet long.

LONDON, ONT.—The C.P.R. will expend about $250,000 here this summer. A station, roundhouse and yards will be built immediately. All the wooden bridges between Toronto and Windsor will be replaced by steel ones.

VANCOUVER, B.C.—Plans are being prepared for an eight-storey business block at the corner of Hastings and Main St. It will be of mill construction.

CALGARY, ALTA.—The C.P.R. will build a $1,000,000 hotel here. Other improvements and extensions here bring the total cost up to $5,000,000.

MONTREAL, QUE.—The Gillette Razor Co. will erect a $100,000 factory on Alexander Street here.

VICTORIA, B.C.—The Dominion Trust Co. will, shortly, erect a six-storey building here at a cost of $135,000.

ESQUIMALT, B.C.—Work will be started at once on the construction of the B.C. Marine Railway Co. drydock here. As it is being built in consideration of the future requirements of the Pacific naval station, it is more than probable that the Pacific Fleet of Canada's Navy will be built here. The local firm is making every effort to secure the contract. It will be 900 ft. by 100 ft. and cost $3,000,000.

SASKATOON, SASK.—J. P. O'Leary, of the Montreal firm of Brown and Vallance, architects, has announced the letting of the contract for the huge 6-storey hotel here to the firm of Carter-Halls-Aldinger Co. The material used in the construction will be terra-cotta and Menominee brick. The structure will have a highly ornamental front and will have both freight and passenger elevators. Cost, $300,000.

WINNIPEG, MAN.—Provincial Architect Hooper is preparing plans for new government buildings to cost approximately $3,000,000. This includes the new Asylum at Brandon, a new agricultural college and new legislative buildings.

TORONTO, ONT.—The C.P.R. are extending their freight and passenger facilities within the city at a cost approximately $7,000,000. The plans include a new passenger depot and freight yard at North Toronto, freight sheds and yards at Christie Street, George Street, Queen's Wharf, Parkdale and West Toronto, with a freight delivery yard at the corner of Bloor and Dundas Streets. There will also be a new office building of several storeys at the corner of King and Yonge Streets, plans of which are not yet complete.

COLLINGWOOD, ONT.—The Northern Navigation Co. will place an order for another passenger and freight steamer to cost about $600,000. The plans will be prepared, tenders asked for from Canadian yards, and the contract awarded in sufficient time to permit of the laying of the keel in July or August next.

VANCOUVER, B.C.—F. D. Boucher will erect an eleven-storey apartment house here at a cost of $300,000.

ST. JOHN, N.B.—Scovill Bros., Limited, intend erecting a modern five-storey building here. A passenger elevator will be installed.

EDMONTON, ALTA.—R. Tegler is calling tenders for a six-storey $100,000 building here.

SASKATOON—A representative of the J. I. Case Co., of Racine, Wis., is here to purchase a site for a warehouse. The building will be one storey high, and 400 feet by 250 feet.

VANCOUVER, B.C.—"Lester Court" is the name of a palatial building to be erected here at a cost of $100,000. It will be of first-class construction, and fireproof steel frame reinforced concrete. It will be lighted with electricity. This is the first of a series of buildings to be erected by A. J. Paterson Co.

BRANDON, MAN.—The provincial government will erect a $50,000 normal school here on Tenth Street. A manual training department is included.

GUELPH, ONT.—The new cold storage and packing plant erected by Chas. W. Barber will be in operation in a short time. It is of stone, concrete and wood. The building is 28 x 98.

STRATHCONA, ALTA.—P. Burns & Co. will erect a new million and a half dollar packing plant here. The big firm has acquired an additional 27 acres adjoining its present site.

EDMONTON, ALTA.—The G.T.P. will construct two tunnels and 24 bridges on the branch line south of Edson, to serve the immense coal areas in the Brazean country.

MONTREAL, QUE.—The C.P.R. has been granted a permit to erect freight sheds on Lacroix Street to cost from $66,000 to $100,000.

PRINCE ALBERT, SASK.—The Modern Automobile Co. will erect here, in the spring, a fireproof brick garage, 50 x 130 feet. It will be one of the most up-to-date garages in Western Canada. Repairs of all kinds will be undertaken.

FORT WILLIAM, ONT.—The Swift Canadian Co. will erect a 4-storey cold storage plant here this summer at a cost of $75,000.

TRADE NOTES.

HAMILTON—The Hamilton Machinery Co. will handle the entire output of the American Road Machinery Co., Goderich; the Canadian sales end of the Keystone Smooth Bottom Corrugated Steel Sewer Pipe Co.; Interstate Automobile Co., Muncil, Indiana. They will handle concrete machinery, wire fence, reinforced concrete wire, mining machinery, etc. They will open branch offices in all the large Canadian centres.

MONTREAL—The Simonds Saw Co., who have a branch factory here for the manufacture of hack saws, etc., have constructed a new steel mill at Lockport, N.Y., the first steel being rolled on January 2.

MONTREAL—The Harbor Commission have installed a new Schumacher & Boye 20-in. instantaneous gear machine lathe in their works here. This machine was purchased from Foss & Fuller.

MONTREAL—Jos. Lacroix, patternmaker, 72 Wellington Street, Montreal, has started work on the construction of his new shop at 143 Wellington Street and will move into his new quarters about May 1st.

The Smart-Turner Machine Co., 191 Barton St., Hamilton, report the following recent orders for their pumps: Canadian Axminster Carpet Co., Hamilton; Rainy River Lumber Co.; Canada Screw Co., Hamilton; Lever Bros., Toronto; G. T. R., Allandale; Gunns Ltd., Toronto; Great Lakes Dredging Co., Port Arthur; Steel Co. of Canada, Hamilton; and Otis Fensom Elevator Co., Hamilton. These pumps include several types designed by the Smart-Turner Machine Co.

MONTREAL.—Ernest Muller, of Schuchardt & Schutte, New York, paid a visit to their Canadian headquarters here, recently.

WELLAND.—The Quality Beds, Limited, have installed a No. 28 Collian Cupola manufactured by Frederic B. Stevens, Detroit.

Gillette Company to Build.

The Gillette Razor Co. have purchased a lot of land on the corner of Dowd & Alexander Streets, Montreal, 100 feet frontage on St. Alexander and 76 on Dowd. They will build here a five-storey fireproof building of mushroom construction. Work will be commenced on the 1st of May next, and will be rushed through as soon as possible.

Foss & Fuller, Montreal.

In a recent issue of Canadian Machinery reference was made to Foss & Fuller, Montreal, a new machinery agency. This firm is now dissolved, Geo. F. Foss continuing the business under the name of Foss & Fuller. Their offices and warehouse at 329 St. James St. are being enlarged to take care of their business which is increasing.

Winnipeg Industrial Campaign.

Secretary Roland of the Winnipeg Industrial Bureau and Controller Waugh of the city government, started on an industrial inquiry trip early in the month. Advices received from them indicate great interest in Western Canada among manufacturers in the United States and give assurance that Winnipeg will soon receive great accessions to her industrial growth. Among the industries which will soon be established in Winnipeg is a process for making textiles from flax straw, which is produced so largely in the West and which now is wasted by burning.

International Harvester Company.

Many improvements have been made at the Hamilton works of this company. These improvements add to the capacity of practically every department at this works, and consist of a paint shop building, 72 x 95 ft., four-storey and basement, of mill construction, and an addition to the gray iron foundry building, 82 x 200 ft., of brick and steel construction; a new mill room building, 142 x 150 ft., two storeys and basement, of brick and mill construction; an extension to the wood shop building, 81 x 100 ft., and a new manufacturing building, 72 x 305 ft., four storeys and basement, of mill construction. A new warehouse in two sections, respectively, 64 x 119 ft. and 100 x 119 ft., four-storey and basement, of brick and mill construction, and a new office building, two storeys and basement, 60 x 103 ft., have also been constructed.

Oliver Chilled Plow Works.

The Oliver Chilled Plow Works have called for tenders on an assembling building, three storeys and basement, 90 x 406 feet, of steel and reinforced concrete, the cost of which is estimated at about $200,000, as provided for in the original plans. This will shortly be followed by the erection of the malleable and gray iron foundry, 135 x 576 feet, one storey, and plans will be prepared for the other buildings as rapidly as possible. The forge and machine shop is already in operation, and the power house will be finished by the middle of the month.

Windsor's New Industries.

Windsor has secured two important industries, the Canadian branch of the Maloney Electric Co., St. Louis, and the plant of the Canadian Winkley Co., a branch of a Detroit concern. The Maloney Co. which manufactures electrical machines, will build a $10,000 plant in the city's factory district at once, while the Winkley Co., manufacturing brass goods, has bought a site in the west end of the city, and will erect a $10,000 plant this year. The by-laws granted exemptions to the two companies.

Coke Ovens of Soo Corporation.

The by-product coke oven plant which H. Koppers, Joliette, Ill., has been building for the Lake Superior Corporation, at Sault Ste. Marie, Ont., is completed. No. 1 battery of 55 ovens is now ready and will soon be producing coke. The brick work on No. 2 battery of 55 ovens is all completed and will be ready to produce coke in a month.

Goldschmidt Thermit Co. Calendar.

The 1911 calendar recently issued by the Goldshmidt Thermit Co., 90 West Street, New York, contains a useful map of North and Central America. Several repairs are illustrated and the application of thermit to marine, foundry and railroad uses, is given. The folder is 20 x 38 inches. The Canadian agency is 109 Richmond St. West, Toronto.

New Tube Works at Montreal.

The construction of the Canadian Tube & Iron Co.'s works is progressing very favorably. The buildings consist entirely of steel and reinforced concrete, making them entirely fireproof and no expense is being spared in the purchase of modern machinery and equipment to enable the company to manufacture at the lowest possible cost. The capitalization of the company is $1,000,000, all common stock, which has been subscribed for privately. The officers of the company are as follows: J. W. McConnell, president; James L. Waldie, vice-president and managing director; Albert H. Hough, sales manager and director; William Mosley,, works manager and director; Herbert Worrall, secretary-treasurer. Directors:—Wm. Molson Macpherson, Dr. Milton L. Hersey, H. A. Lovett, K.C.

The buildings are now nearing completion, and it is expected that the company will start manufacturing early in the spring. The works are situated on a large tract of land which has been obtained by the company at Cote St. Paul, Montreal.

Canadian General Electric Enlarging.

The Canadian General Electric are planning to erect a large lamp factory and new offices in Peterboro'. The lamp factory will be 60 x 125 ft. and will cost $250,000.

CATALOGUES.

Calendar.—The city of Winnipeg has sent out a large calendar featuring that place as the hub of industry, to which all roads lead. It was very cleverly arranged, and contains a handy index of information, relative to Winnipeg, aptly termed, "an open book of opportunity."

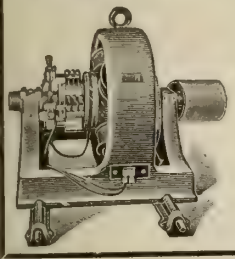
Friction Clutches.—The Dodge Mfg. Co. have issued a 16-page catalogue describing Dodge split and solid clutches. The economic features are dealt with and the construction of the clutch is given in detail. A two-page table shows the sizes manufactured together with full information in regard to h.p. transmitted, speed, face of pulley, cost, etc.

Chain Drive.—Jones & Glassco, Montreal, have published an interesting folder giving approximate comparative costs of electric power using belt and chain drive. In a list of Canadian towns given, the saving per useful horse-power per year by using chain instead of belt varies all the way from $2.42 in Toronto up to $12.38 in Calgary. In this comparison it is pointed out that the calculations are based on the maximum efficiency (80 per cent.) of belt drive but the minimum efficiency (95 per cent.) of chain drive.

Milling Machines.—The Garvin Machine Co., Spring and Varick streets, New York City. Circular No. 142 contains a description of the Nos. 14 and 15 vertical spindle milling machines for machining castings which require the finishing of surface joints. No. 143 refers to the use of the No. 3 duplex milling machine, one of the special advantages of which is the finishing of two sides of the work perfectly parallel at the same time.

Electric Welders.—A handsome calendar of 35 pages on coated paper, size 6 x 9 inches, from the Toledo Electric Welder Co., Cincinnati, describes their various types of electric welding machines. One of these welders is shown embossed on the front cover, making a very attractive cover design. Several pages are devoted to "Electric Welding Machines—What they can do and how they do it." The last few pages are devoted to valuable data for use in connection with welding machines and shop practice.

Book Review.



"The Effect of Keyways on the Strength of Shafts," by Herbert F. Moore, has just been issued as Bulletin No. 42 of the Engineering Experiment Station of the University of Illinois. This bulletin records the results of tests made to determine the relative strength of solid shafts and shafts with keyways. Various sizes of shafts were tested and for each size of shaft the weakening effect of keyways of several proportions was determined. Tests were made on shafts subjected to twisting only and on shafts subjected to twisting and bending at the same time. The results show that the weakening effect of keyways of the usual proportions upon the strength of shafts is considerable, a square keyway of the usual size causing a reduction of about one-sixth in the strength of the shaft. Formulas and a diagram are given for determining the effect of keyways of various proportions. The effect of keyways for the Woodruff system of keying is discussed. The results of the tests are summarized in a table showing the power which can be transmitted by various sizes of shafts with keyways of usual proportions. Copies of Bulletin No. 42 may be obtained gratis upon application to W. F. M. Goss, Director of the Engineering Experiment Station, University of Illinois, Urbana, Illinois.

The Mechanical World Pocket Diary and Year Book for 1911.—Twenty-fourth year of publication. Size, 4x6 in.; pages, 423. Bound in cloth. Price, twelve cents, net. Published by Emmott & Co., 65 King Street, Manchester, England.

In presenting this yearly revised engineers' pocket-book, some 32 pages have been added, and by carefully revising and condensing, space has been provided for the introduction of a large amount of new matter. Among the special features of this edition are a lengthy section on the shapes, speeds and feeds of cutting tools with supplementary sections dealing with milling cutters and twist drills. The section on standard screw threads is entirely new, and that dealing with screw cutting has been extended considerably. Other new sections deal with high speed steel and the constructive details of gas engines. Several additions have been made to the tables of weights, measures, etc., and a new table of steam fittings and tables and data on marine boilers, rivetted joints, etc., are included.

STARRETT TOOLS

ARE THE STANDARD

FOR ACCURACY, WORKMANSHIP, DESIGN AND FINISH

In our tapes the figures denoting feet are smaller than those denoting inches. Two reasons for this:

This dissimilarity of figures materially lessen (in fact ought to entirely prohibit) the liability to erroneous readings that frequently occur through the uniformity of all figures in steel tapes of all other makers.

The smaller figures denoting feet allow the graduation line under each to be plainly visible, instead of being obliterated by the usual larger figure.

Graduated in feet, inches and eighths of an inch, or in feet, tenths and hundredths of a foot.

Our Furnaces Heat Steel with the Cheapest Fuel on Earth—
SOFT, SLACK COAL

They are all fired with "American" Mechanical Stokers, which burn bituminous slack coal automatically and without smoke, and give a clear, steady, soft, non-scaling flame. You get increased production, at about one-third to one-half the operating cost of oil or hard coal. This is a fact. If you burn money to heat steel why not burn less of it, and write us at once?

Applicant has had extensive training in correspondence and in advertising, general publicity work and sales manager. References exchanged. Address Hustler, c/o CANADIAN MACHINERY, Toronto.

LIVE MAN, thoroughly practical and theoretical. Experienced improving machine shop methods and efficiency. Piece work; time study; demonstrating. Tactful and diplomatic in handling men. Excellent references. Box 108, CANADIAN MACHINERY, Toronto. (2)

MISCELLANEOUS.

A BOOK-KEEPING STAFF IN ITSELF — doing the work with machine precision and accuracy, the National Cash Register. Write us for demonstration literature. National Cash Register Co., 285 Yonge St., Toronto.

ACCURATE COST KEEPING IS EASY if you have a Dey Cost Keeper. It automatically records actual time spent on each operation down to the decimal fraction of an hour. Several operations of jobs can be recorded on one card. For small firms we recommend this as an excellent combination—employees' time register and cost keeper. Whether you employ a few or hundreds of hands, we can supply you with a machine suited to your requirements. Write for catalog. International Time Recording Company of Canada, Ltd. Office and factory, 29 Alice Street, Toronto.

COPELAND-CHATTERSON SYSTEMS — Short, simple. Adapted to all classes of business. Copeland-Chatterson-Crain, Ltd., Toronto and Ottawa. (tf)

COUNTER CHECK BOOKS — Write us to-day for samples. We are manufacturers of the famous SURETY NON-SMUT duplicating and triplicating Counter Check Books, and Single Carbon Pads in all varieties. Dominion Register Co., Ltd., Toronto.

DOUBLE YOUR FLOOR SPACE. An Otis-Fensom hand-power elevator will double your floor space, enable you to use that upper floor either as stock room or as extra selling space, at the same time increasing space on your ground floor. Costs only $70. Write for catalogue "B." The Otis-Fensom Elevator Co., Traders Bank Building, Toronto. (tf)

ELLIOTT-FISHER STANDARD WRITING-ADDING MACHINES make toil easier. Elliot, Fisher, Limited, Room 314, Stair Building, Toronto.

MISCELLANEOUS.

DURING 1910 the MONARCH displaced hundreds of Typewriters of all makes. In 1911 we anticipate a still greater demand. We have cut down the allowance on these second-hand machines and consequently can sell them cheaper to you. They are carefully rebuilt and are guaranteed to give satisfaction or your money back. If you want a good, strong, clean working Typewriter at a mere fraction of the original cost, write us for catalogue. THE MONARCH TYPEWRITER CO., Ltd., 46 Adelaide Street West, Toronto, Ont.

EGRY business systems are devised to suit every department of every business. They are labor and time savers. Produce results up to the requirements of merchants and manufacturers. Inquire from our nearest office. Egry Register Co., Dayton, Ohio; 123 Bay St., Toronto; 258½ Portage Ave., Winnipeg; 308 Richards St., Vancouver.

FIRE INSURANCE. Insure in the HARTFORD. Agencies everywhere in Canada. (tf)

GET THE BUSINESS—Increase your sales—Use Multigraph typewritten letters. The Multigraph does absolutely every form of printing. Saves you 25 p.c. to 75 p.c. of your printing bill. Multigraph your office forms, letterheads, circular letters. Write us. American Multigraph Sales Co., Ltd., 129 Bay Street, Toronto.

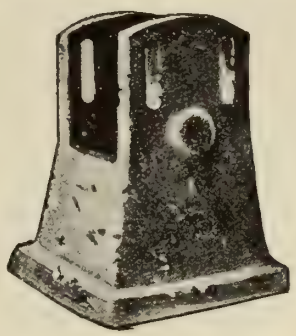
Insure your profits

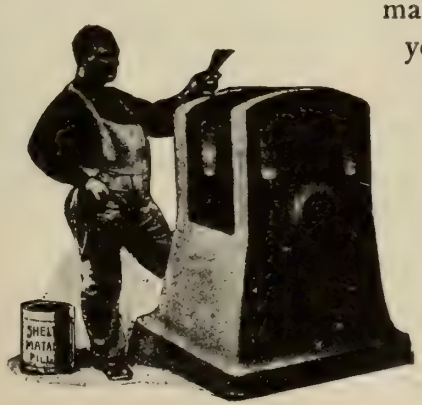
For the *NEW YEAR* by using



SHELTON METALLIC FILLER

What did your loss in Castings cost you for last year? Figure up the **lost time**, the **disappointed customers**, the **reduced output**, the **"scrap-heap!"**

You will find that it cost you a CONSIDERABLE SUM.

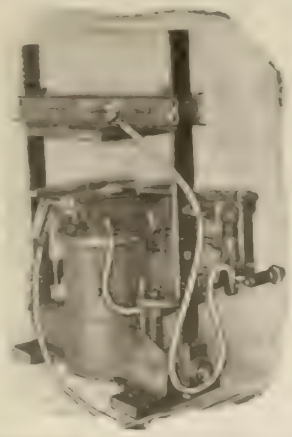


Would it not be wise to cut out these big items of expense?

YOU CAN DO IT.

For a mere trifle, castings like this can be made perfect, and will pass any inspection.

Shelton Metallic Filler is a guarantee for bigger profits in any foundry.



SHELTON METALLIC FILLER will make all castings perfect---it will save you time---it will insure prompt shipment to awaiting customers---it will increase your output---it will make your "scrap-heap" a thing of the past!

Shelton Metallic Filler fills in and completely obliterates blow-holes, sand-holes, etc. It becomes part of the casting itself, looks like the casting, and is as durable. It cannot be detected. If you are not using it, **give it a trial.**

Increase Your Salary
$5.00 to $10.00 Per Week

Acting as circulation representative for the MacLean Publishing Company is in itself an excellent business training.

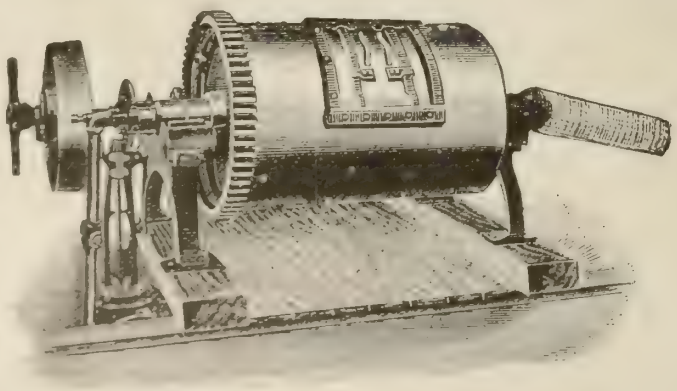
By looking after the new and renewal subscriptions of their thirteen publications you can increase your present income at least $5.00 each week.

One hour a day is ample time to enable you to earn this salary.

Competent representatives will be given charge of our entire business in their respective towns—securing renewal orders, also new business.

This work is pleasant and does not require experience.

No matter what size your town may be there is plenty of opportunity for a circulation representative of The MacLean Publishing Company, to earn five dollars every week, in addition to his present salary.



Write at once for particulars.

MacLean Publishing Company

143-149 University Avenue : : : : Toronto, Ontario

A GOLD MINE

SAVE YOUR IRON

SLY'S PATENT IRON CINDER MILL

Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the coke contained in your cupola dump, and gangway scrapings. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paying for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

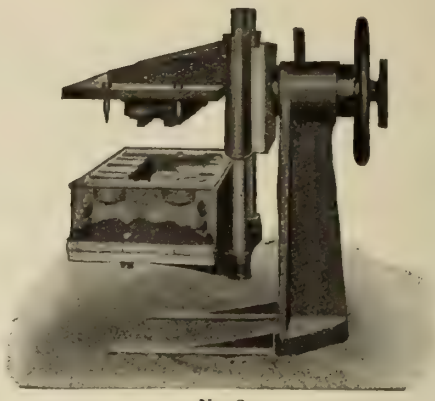
Tallman Brass & Metal Co.

HAMILTON, ONT.



Grimes Roll-Over Molding Machine

No. 1

This is a simple, standard machine, requiring small floor space.

It is perfectly balanced, requiring no counter-balancing mechanism, as centre of gravity is centre of rotation.

No. 2

By means of small hand wheel shown in cut, one man can turn largest flask smoothly and without jerk.

Pattern is drawn by absolutely straight gravity drop.

This machine is adjustable for deep flasks and can readily take care of flask 24 in. x 36 in. and 4 to 12 in. in depth, with maximum pattern draft of 12 in.

Positive adjustable pins at four corners of clamping device, Fig 2, compensate for unevenness of floor boards.

PRICE, f.o.b. cars Windsor, $125.00

HIGH GRADE CASTINGS are not made with low grade materials. Think this over when you see a poorly finished casting in your cleaning room, and remember, if you please, if you wish to place the pattern in the high grade class, our No. 48 Plumbago will do it, also that the saving in cleaning room expense would pay for three times the necessary No. 48 Plumbago to have made it high grade.

Another vital point is that you have a core wash which will peel clean and not run before the metal. Try our Eureka Blacking, the best core wash on the market.

THE SELECTION OF FIRE BRICKS

Sole manufacturers of KING Fuel Oil Furnaces for all heating and melting purposes

Fire Bricks are a necessary item of expense and, as such, should be given careful consideration. This expense is only kept on a minimum basis by using the most suitable fire brick to meet the exact conditions of service.

The purchase price of Fire Bricks does not indicate their cost.

It is the life of the Fire Brick which demonstrates whether you are getting full value for the money invested.

In addition to being required to withstand heat, Fire Bricks are frequently subjected to one or more of the following conditions:

1st. Chemical action of powerful fluxes and slags.

2nd. Reducing action of gases.

3rd. Sudden heating and cooling with wide temperature variations.

4th. Pressure and grinding action.

5th. Abrasion.

6th. Cutting and impinging flame.

7th. Combination of one or more of the above with heat.

No matter what your needs are, we have a brick which will give you satisfaction.

Our technical department is ready at all times to offer suggestions which will eliminate your fire brick troubles.

Protect yourself against tedious delays and costly experiments by buying your fire bricks from us—who know this business from A to Z.

The best known brands on the market to-day are our WOODLAND, H.W. SPECIAL, MUNRO, BONNYBRIDGE, KIRKWOOD.

Quality

Our proposition on Drill Chucks is to make superior Drill Chucks so much better than anyone else makes, that our customers will do all the talking necessary to increase our business. The fact that we have, in the seven years we have been in business, sold more than 90,000 JACOB IMPROVED DRILL CHUCKS, is the most positive proof that our aspiration has been realized.

Don't be imposed upon with inferior imitations. Insist upon having the genuine JACOBS IMPROVED DRILL CHUCKS. On each of these CHUCKS is printed: "THE JACOBS MFG. CO.,—HARTFORD, CONN., U.S.A.—PATENTED SEPT. 16, 1902."

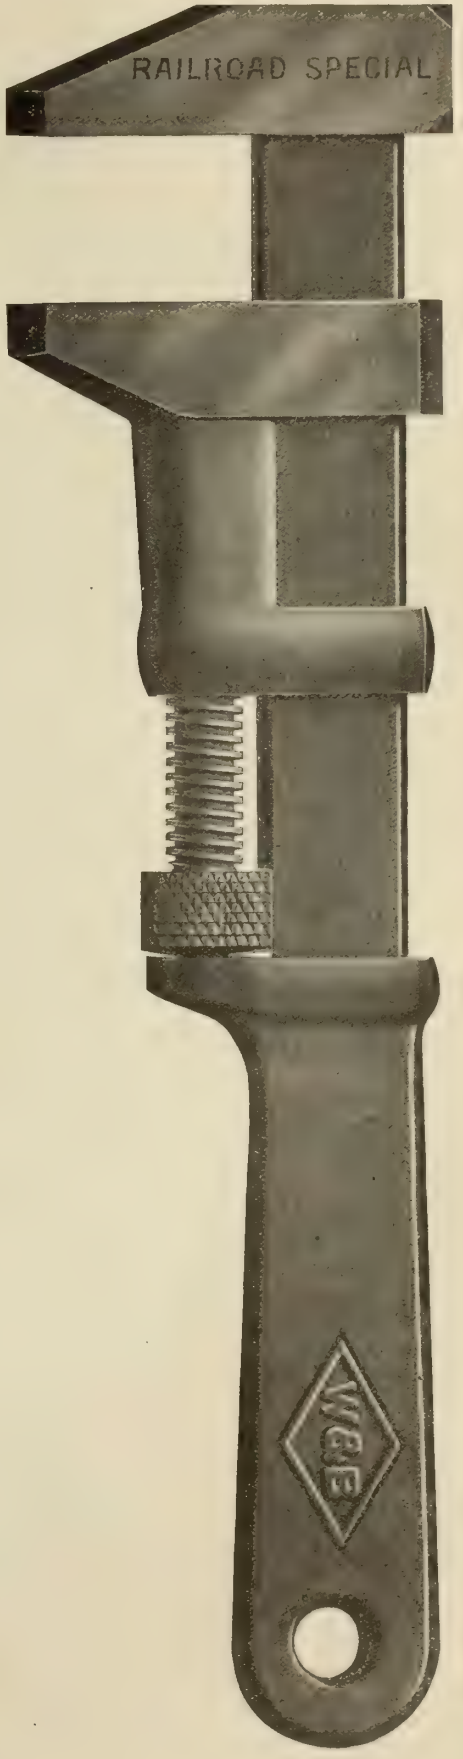
THE



Wrench for Service

AND THE MOST EXACTING SERVICE IS THE

"RAILROAD SPECIAL"

IT is the strongest wrench made—barring none—because the head and bar are drop forged in one piece from open hearth steel and all parts are very heavy and of the best material. It is fitted with our iron handle, which fits the hand and is practically indestructible. Adapted for use by Mills, Factories, Shops, Railroads and in all other places where a strong, serviceable wrench is required.

Used by the largest railroads in the world because it saves them money.

W B CO **TRADE MARKS** W&B

WE MANUFACTURE THE LARGEST AND MOST COMPLETE LINE OF WRENCHES IN THE WORLD.

Carborundum—The Uniform, Durable, Fast Cutting Grinding Wheel

In grinding Bessemer steel shafts in a big Eastern machine building plant Carborundum Grinding Wheels cut faster, last longer and are more uniform in quality than any other grinding wheels that have ever been tried.

The shafts are 72 inches long and $1\frac{15}{16}$ inches in diameter. Carborundum Wheels remove the stock at the rate of one hundredth of an inch, with but two thousandths of an inch wheel loss—Fast cutting and durable. Another important fact—Corborundum Wheels invariably retain an absolutely true surface—uniformity—The operator says that Carborundum Wheels are the **only** ones with which he can get these results.

It would be to your advantage to let us know about *your* grinding problems. We can help you to maximum results by giving you the right wheel for the right place.

A reliable machine, handily operated, means accurate work quickly done.

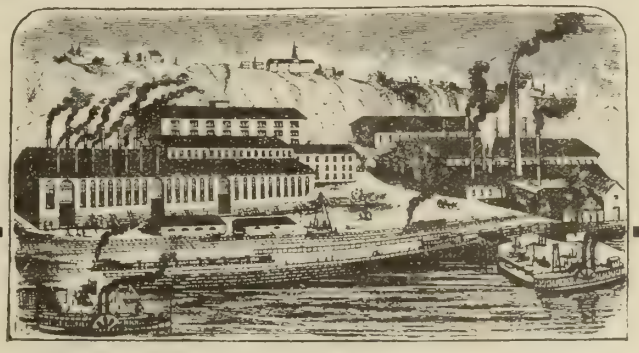
No. 6 WIRE FEED SCREW MACHINE

with Roller Feed

In a machine where the object is the production of duplicate parts in small lots, every feature which facilitates operation and insures accuracy, is worth considering. Take the manner of holding the stock and the feed ; they are important.

The CHUCK must hold the stock and also permit of quick adjustment for different diameters This is provided by adjustable jaws which can be easily and rapidly adapted to different sizes, after the principle of a universal chuck. This is also an economical feature, as it does away with the large set of expensive collets to fit different sizes.

The ROLLER FEED furnishes a quick and accurate method of feeding the bar forward. It can be easily and quickly adjusted, graduations on the front of the disk facilitating the setting for any size of stock. It is located close to the chuck and will act equally well with a long bar or when a short piece remains. A lever on the front of the headstock operates both chuck and roller feed with one movement



If you have work to do send us a blue print and we will estimate on the cost, pieces per hour, etc., that can be done on this machine.

Brown & Sharpe Mfg. Co.

Providence, R.I., U.S.A.

MARINE ENGINES and PUMPS. SHOE MACHINERY A Specialty

BRASS and IRON CASTINGS. BOILERS and REPAIRS.

That we have exceptional facilities at our disposal for the manufacture of all kinds of Machinery—in addition to our business as Brass and Iron Founders, General Contractors and Shoe Machinery Engineers—has been amply proved this year. In the short space of five months, we built and installed all the Engines and Boilers of the new sister steamers "Levis" and "Lauzon," whose trial trips were a complete success. We make a specialty of all kinds of Marine Engine Work, and shall be glad to quote for first-rate products only.

SHOE MACHINERY. Manufacturers of "Non-Royalty" Machines, Metallic and Goodyear, "Fortuna" Skivers, and "Climax" Presses, Sand-papering, Lasting and Loose Studding Machines.

Wire of every description for Slugger and Standard Screw Machines.

INCREASED EFFICIENCY Means INCREASED PROFITS

THIS new gap lathe, with its extra speed and absolutely rigid construction, will increase the efficiency of any shop. Notice the extra strong construction of the gap. The carriage and apron also are so constructed that they will not spring under the most severe strain. The head stock will not chatter. The tail stock is adjusted from the top, saving much of the operator's time. Friction safety feeds give quick changes of thread and double back gears give eighteen distinct spindle speeds. In every way this new Gap Lathe will prove to be a paying investment. Full equipment is supplied with each lathe.

Headstock construction prevents chattering, and deep oil chambers fitted with ring oilers make spindles and bearings self-oiling and always well lubricated.

Tailstock of a special type, and sleeve is clamped by a quick acting locking device. Tailstock is secured to bed by bolts adjusted from the top where they are easily accessible.

Bed, non-springing and webbed, and braced to secure rigidity.

Gap, vibration absolutely prevented by use of brace supports to carriage.

Spindle, high carbon hammered steel in solid chilled cast iron bearings, accurately fitted and self oiling.

Carriage and Apron, non-springing under severest strain, full "V" bearings and flat bearings in addition on front ways.

Double Back Gears give eighteen distinct spindle speeds, suiting lathe to work on widely different diameters.

Compound Rest, with graduated base, accurately fitted taper gibs, end adjusted. Screws in both rest and cross slide read to thousandths.

Friction, Safety Feeds, screw and rod feeds cannot be both engaged at the same time. Quick changes of 1¼, 2½ and 5 times thread being cut.

Gears and Racks, cut from solid and steel where necessary.

Screw Cutting, full range of commercial threads provided for.

Equipment, Compound rest, steady rest, follow rest, large and small face plates, wrenches, two speed, friction countershaft furnished with each lathe.

Accuracy, Strength, Solidity, Wear. These are the paramount features behind all McDougall Machines. Made **to meet extreme demands.**

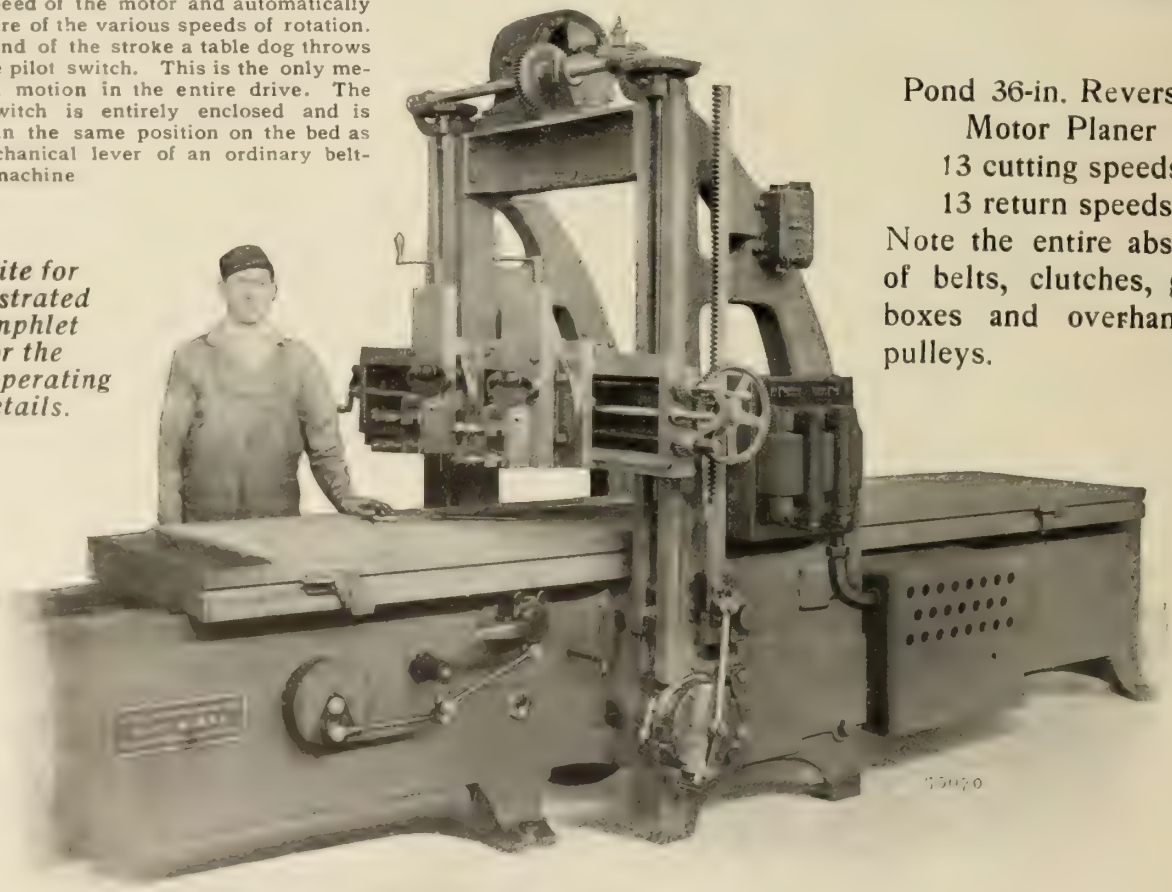
Variable Speeds Without Complication

Without Resorting to Clutches, Belts or Sliding Gears

IN the Pond Reversing Motor Planer is offered an entirely new method of driving and reversing at variable speeds. This system is the result of years of experimenting in this line, and has proven itself absolutely reliable under the most severe and adverse working conditions. It overcomes all the undesirable features of belt and gear-box drives and does away with all clutches, either pneumatic or magnetic, all shifting belts and all sliding gears.



The reversing drive essentially consists of one motor which acts as a generator at the instant of reversal. This result is accomplished automatically by a patent controller. On the controller are mounted two index scales—one controls the range of cutting speeds and the other the return speeds. Each scale is provided with 13 graduations or divisions, by means of which an equivalent number of different motor speeds are obtainable by simply sliding the thumb piece on the scale. There are no dash-pots in the system

Pond Reversing Motor Planer

With reversing motor connected direct to pinion driving shaft

The cutting speeds obtainable on the standard type of planers vary from 25 to 40 feet per minute, and the return speeds from 60 to 100 feet. However, these speeds can be changed to suit any individual requirements. The cutting and return speeds are entirely independent of each other, so that it is possible to use the slowest cutting speed and the highest return speed, or vice versa. The table is reversed by adjustable dogs which throw the controller into the dynamic position, the current which is generated at this instant bringing the motor to a stop.

At the instant of reversal, in which the motor is being brought to a stop, the controller automatically reverses the main circuit to motor, which gives the reverse direction of rotation The dynamic feature of the controller is absolutely dependent upon speed of the motor and automatically takes care of the various speeds of rotation. At the end of the stroke a table dog throws over the pilot switch. This is the only mechanical motion in the entire drive. The pilot switch is entirely enclosed and is placed in the same position on the bed as the mechanical lever of an ordinary belt-driven machine

Pond 36-in. Reversing Motor Planer
13 cutting speeds
13 return speeds
Note the entire absence of belts, clutches, gear-boxes and overhanging pulleys.

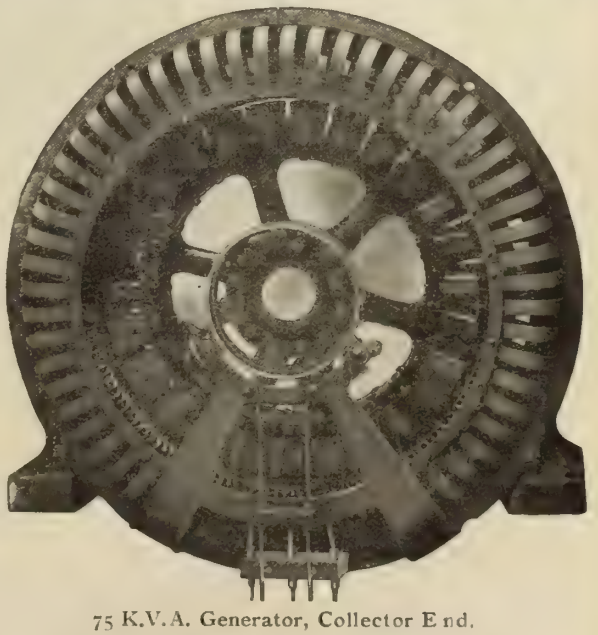
Three Measurements At One Setting

¶ The S & S Vernier Caliper is a clever combination of three precision measuring tools. The inside diameter, outside diameter and depth are obtained at one setting, without deduction. ¶ This is the only caliper on the market having the convenience of a depth measure. The accuracy of this tool is that found only in first class makes.

$3.10

This price includes a genuine leather case. It fits easily and comfortably into your side pocket and is always at hand ready to take measurements of any nature. Stamped with the firm's name without extra cost when reasonable quantities are purchased. Write for Circular. *Liberal discount to dealers.*

Schuchardt & Schutte



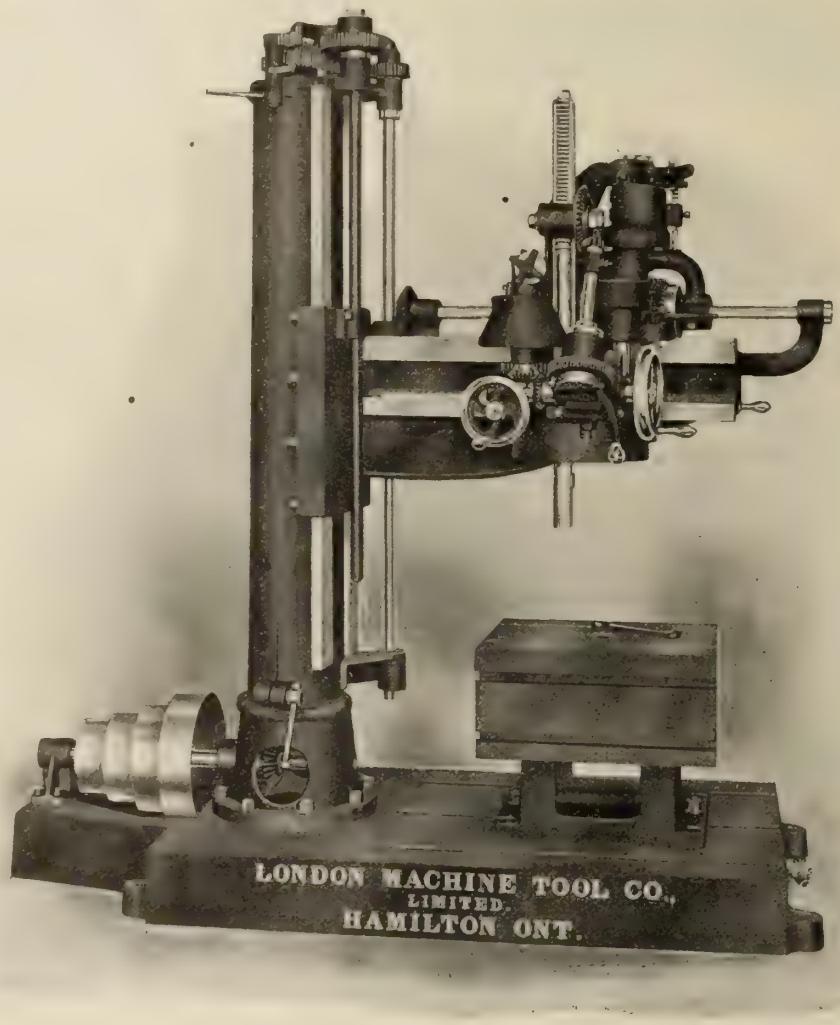
307 Coristine Bldg., MONTREAL, QUE.

Westinghouse Engine-Type Alternating-Current Generators

50-1100 Kva. 60 Cycles. 240-2400 Volts.

This line of slow speed generators is arranged for direct mounting of the rotor on the engine shaft, which, together with the bearings, is supplied with the prime mover.

Economic use of properly distributed materials and general excellence of design and construction are united in the construction of these generators. For moderate first cost, consistently satisfactory performance and low maintenance charges, these machines are unsurpassed by any alternating-current generators on the market. They are specially suited for industrial isolated plants and moderate capacity central stations.



75 K.V.A. Generator, Collector End.

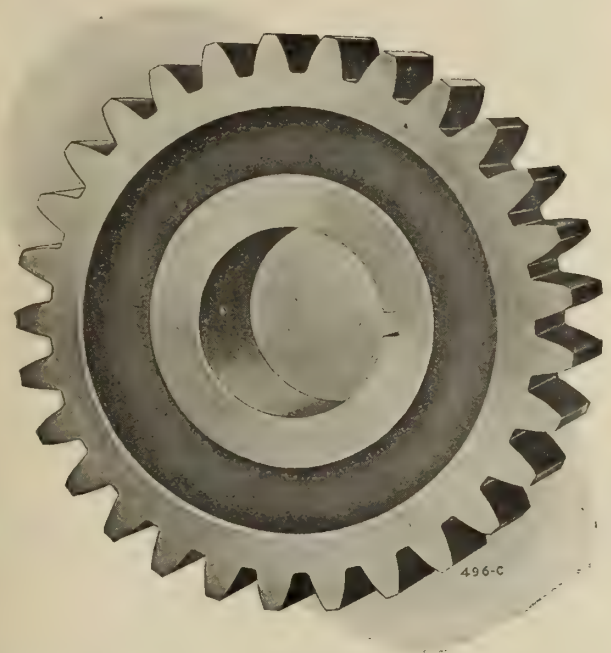
Becker Vertical Spindle Milling Machines

New Model "C" for Heavy Milling

Some Features of this Machine



THE QUESTION OF POWER CONSUMPTION is one needing special consideration. It is generally considered that all-gear driven spindles consume much more power than an open belt driven machine. Model "C" Vertical can be driven by a 5h.p. variable speed motor. Tests made show a consumption of 4 electrical h.p. when removing 20 cubic inches of cast iron per minute, and when milling soft steel at the rate of 10 cubic inches per minute a 5h.p. consumption. We solicit a comparison of this test with results made by all-gear driven vertical milling machines.

THE ADVANTAGES OF OPERATING A MILLING MACHINE SUCCESSFULLY on heavy cuts without back gears in mesh is too well known to need enlarging upon. We desire only to call special attention to the fact that the Model "C" is designed to perform satisfactorily the average work in the average shop without any spindle gears in mesh. Constant torque of the spindle under direct belt action insures smooth work and reduces chattering, thus making the new Becker a power in its field.

Full specifications on request. Catalogue 56C for general description.

THE BECKER MILLING MACHINE COMPANY, HYDE PARK, MASS., U.S.A.

The Cincinnati High Power Gearing

One of the Cincinnati forged steel, spindle driving gears, with accurately cut teeth having 20 degrees pressure angle. Note the great strength indicated by their large root section.

ALL the spindle drive gears on our High Power Millers are made from steel forgings.

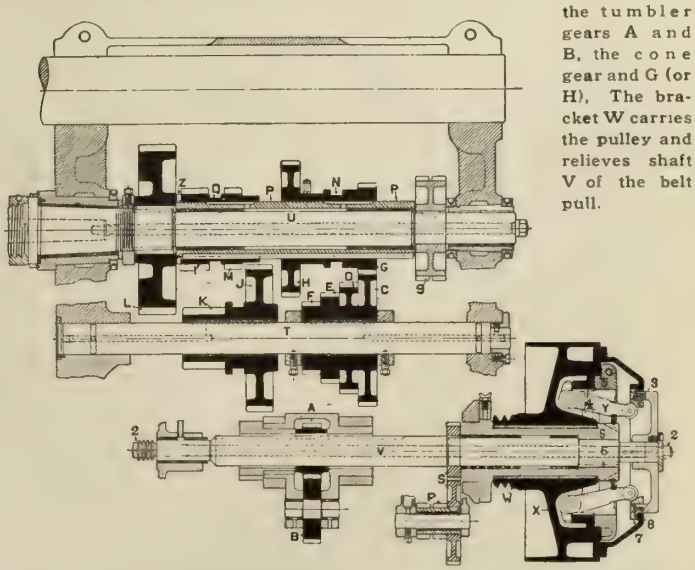
Our gear teeth have 20 degrees pressure angle which produces teeth having an unusually large root section and correspondingly increased strength.

Our gear train is of the simplest form.

There are only 12 gears altogether between the driving pulley and the cutter. Only a few of these are used at one time. For example—each one of the eight fast speeds is obtained by driving through only the two tumbler gears, the cone gear and one of the sliding gears; only one gear more than has always been used on the ordinary single back geared machines.

The eight slow speeds employ the additional gears, I J K and L, which provide a total Back Gear Ratio of 25 to 1 on the larger machines.

All the other gears, in each case, are idle, held in reserve ***For Providing Changes In Speed.***



None of the shafts are subjected to combined bending and torsional strains. All shafts are supported in adequate bearings at both ends.

The pulley runs on a bracket (W), relieving the driving shaft of the belt pull.

Transmission for all speeds is through the face gear keyed to the spindle close to the front box, relieving the length of the spindle from torsional strains.

Never any gears in mesh except those needed to give the speed being used. Tumbler automatically clamped to its bearing on the machine frame at each one of its positions, eliminating vibration in these parts.

The Cincinnati gear train set for one of the eight fast speeds, which use only the tumbler gears A and B, the cone gear and G (or H). The bracket W carries the pulley and relieves shaft V of the belt pull.

Carborundum—The Uniform, Durable, Fast Cutting Grinding Wheel

In grinding Bessemer steel shafts in a big Eastern machine building plant Carborundum Grinding Wheels cut faster, last longer and are more uniform in quality than any other grinding wheels that have ever been tried.

The shafts are 72 inches long and $1\frac{15}{16}$ inches in diameter. Carborundum Wheels remove the stock at the rate of one hundredth of an inch, with but two thousandths of an inch wheel loss—Fast cutting and durable. Another important fact—Corborundum Wheels invariably retain an absolutely true surface—uniformity—The operator says that Carborundum Wheels are the **only** ones with which he can get these results.

It would be to your advantage to let us know about *your* grinding problems. We can help you to maximum results by giving you the right wheel for the right place.

THE CARBORUNDUM COMPANY

NIAGARA FALLS, N.Y.

OUR
No. 264 SELF-FEED RIP SAW

Embodies in its construction all features that are necessary for the satisfactory handling of light or heavy material.

No. 264 Self-Feed Rip Saw.

It is equally efficient in ripping SHORT or LONG Stock. Both the in-feeding and out-feeding roll may be adjusted close to the saw, permitting short stock to be fed without trouble.

The Feed Rolls may be instantly raised, converting it into a hand-feed machine when desired.

The table raises and lowers to accommodate different thicknesses of stock.

Capacity—Rips 4 in. thick with a 16 in. saw, and 8 in. with a 24 in. blade. Takes 19 in. between saw and fence.

A High-Grade Small Engine Lathe at Moderate Cost!

With or Without Quick Change Gear Device.—Three or Five Step Cone. You can use one in YOUR shop.

FREE from fussy attachments and mere talking points, the Von Wyck 15-inch engine lathe offers such a combination of convenience and economy that operators maintain, "It is unequalled by any lathe of its swing."

WHY buy a large size and pay a big price to get great strength and efficiency? Von Wyck design and construction are thoroughly high grade in every important detail and satisfactorily cover an unusual range of work.

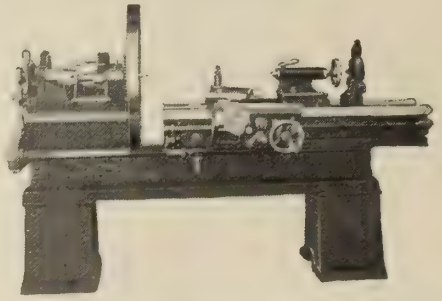
Valley City No. 3

This Tool and Surface Grinder has an unequalled production range where quantities of key-fitting, punch, die and tool sharpening are concerned.

Base is cast solid to avoid vibration and permit high speed. Convenient and rigid knee and table operated by hand wheel, holds work solidly in any desired position.

Table, 11 x 20 inches, has a vertical travel of 12 ins. on the guides and may also be equipped with a reversible sliding table.

Floor space required, 28 x 20 inches. A very convenient all-around machine for general shop or tool room grinding.



Send for catalog of grinding and polishing machinery.

Valley City Machine Works
GRAND RAPIDS, MICH.

EIGHT-FOOT CENTERS on an eight-foot bed.

TWENTY-EIGHT INCH SWING on a fourteen-inch lathe,

all for a little more than the price of a small lathe, and at HALF THE PRICE of a large lathe.

14 x 28 x 8 Extension Gap Lathe.

For large work the top bed is moved by power out along the base, opening the gap, making a large swing lathe with increased center distance. The overhanging carriage is supported by a bracket with adjustable gib, making a rigid design, capable of turning full swing diameters to the best possible advantage. The triple-geared face plate furnishes ample driving power.

Seven sizes of these we build, and all as good.

The new book is yours for the asking.

A REMARKABLE TEST OF

MAGNOLIA

By the United States Government Using Water as a Lubricant

The "No. 2 Magnolia" mentioned in "TABLE E" contained the same proportions of tin, antimony and lead as the genuine "No. 1 Magnolia," but did not contain graphite nor was it treated by our special foundry process; however, it was made of virgin materials mixed in the ordinary way, and would class as a high grade babbitt.

TABLE E.—Giving results of combined ahead and reverse for friction test of Magnolia and "A" White Brass for each change of weight for 100 lbs. per square inch to 600 lbs. per square inch of projected area of bearing surface by increasing weight 100 lbs. per square inch at each change. **Lubricant: water.**

A " White " Brass could be tested up to only 200 lbs. per square inch, as the machine would not turn beyond that weight.

The Testing Machine turned easily up to 600 lbs. per square inch with the genuine Magnolia No. 1.

It was not thought necessary to test the No. 2 metal beyond 200 lbs. per square inch. The Water Test shows the true intrinsic value of Magnolia Metal as compared with other metals. It also demonstrates that a metal may show relatively the same analysis as Magnolia and yet fall far short of giving equal results; it also shows the destructive effect of frictional heat on even a very hard metal like white brass.

It will be observed that the genuine Magnolia Metal (No. 1) proved to be twelve times superior anti-frictionally to white brass, and three times superior to the No. 2 or ordinary grade babbitt.

SILENT CHAINS

What Users Think

¼ to 1000 H.P. transmitted

Messrs. Jones & Glassco,
Montreal

Montreal, Feb. 8th, 1909

Renold Silent Chain Drive

Gentlemen,

In reply to your inquiry of January 30th. I may say that the Renold Silent Chain Drives we have installed are giving every satisfaction.

Our first drive was installed to replace a 12-inch belt which was giving us trouble on account of short centres; this chain has run continuously for four years without the slightest trouble.

Our second drive was installed on a mixing machine doing heavy duty and which had previously broken up two sets of spur gearing; this chain has run over three years with no sign of wear yet.

Our third drive was installed on a calendering machine after breaking two sets of helical gears, and this has been so successful that we are now installing two more similar drives,

I would be perfectly willing to make an appointment with any person genuinely interested and show him the drives in operation.

The above comes from one of the largest manufacturers in Montreal, and is signed by the Mechanical Superintendent. Up to the present (1911) these drives have not received repairs of any kind.

The Safeguarding of Machinery in Industrial Plants

The Importance of Safeguarding Machinery was Pointed out at a Recent Meeting of the American Society of Mechanical Engineers When John Calder gave a Paper Discussing the Nature and Incidence of Industrial Injury, its Prevalence and High Rate, and the Present General Desire for better Conditions of Safety. It Analyzes the Chief Causes of Injury as Revealed from a Study by the Author of a Large Number of Verified Casualties and Recommends Practicable Measures Calculated to Reduce the Present Numerous Fatalities and Injuries. It Discusses in Particular the Important Services Which the Mechanical Engineer, both as an Executive and Constructor, can Render in Exercising his Ingenuity to Avoid Industrial Accident. The Paper Contains a Number of Practical Safeguarding Illustrations from the Field of Machine Building, Equipment, Installation, Transmission Plant and Especially Dangerous Machines and Processes, and Concludes with Suggestions for Administrative and Remedial Precautions.

THE subject of accident prevention is now coming to the front on that wave of humanitarian consideration which is noticeable everywhere. On its educational and sentimental aspects mechanics, foremen, superintendents, managers and proprietors have had their interest awakened to some extent by the work being done by manufacturers of safeguards and by manufacturers generally realizing that every workman laid aside from work means a break in the organization, and hence a decreased efficiency in the shop.

The principles of safeguarding and safeworking in industry should be as much a part of the economic education of the young engineer and the future (and present) shop officials, as those of efficiency. The scientific study as a matter of course and the solution by the mechanical engineer of individual problems of safeguarding, supervision and instruction of employes as they arise in their daily routine will do more than all other existing agencies to bring about satisfactory results.

It is believed that, by proper supervision and precautions in all plants and

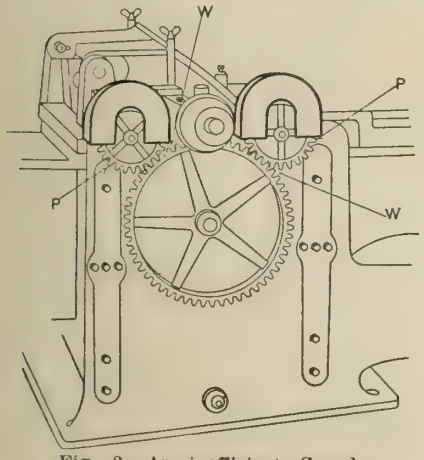

Fig. 2.—An inefficient Guard.

industrial processes and the cultivation of greater care by operatives, at least one-third of the present annual sacrifice of life and limb can be prevented.

The Cause of Accidents.

The word "accident" in relation to industry is not specifically defined by any statute, but it has the popular significance of any unforeseen and usually sudden occurrence which results in bodily injury to any person while present at the work place or even within the boundaries of the employer's premises. The injury, to be reportable as an accident,

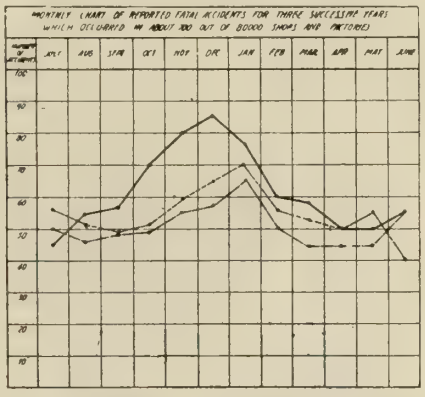

Fig. 1.—Influence of Daylight on Accidents.

need not arise out of or in connection with the employe's assigned duties. It is the fact of injury, not the cause, which generally makes an accident reportable under the labor laws to the civil authorities.

In analyzing many thousands of industrial accidents, the following have been found to be the chief causes: Ignorance, carelessness, unsuitable clothing, insufficient lighting, dirty and obstructed workplaces, defects of machinery and structures, and absence of safeguards. In current popular comment on the wastefulness of life and limb in our industrial regime little regard is paid to the facts underlying accident, but well considered action must be based solely on these of which some account follows:

In spite of ample facilities now afforded to all for the acquisition of some knowledge of mechanical principles, some superintendents, a number of foremen, many operatives and not a few managing owners of smaller plants, have been found to be grossly ignorant of the nature of the forces and mechanical arrangement which it is in their power either to control or to set free with resulting danger to themselves and others.

Sometimes combined with ignorance, sometimes sheer thoughtlessness, folly or horse play, carelessness by operatives stands highest as a cause of industrial accident from the results of which nothing external can do much to shield the worker and those whom he sometimes involves. It is the experience of the author that the American workman is easily first in taking foolish and wholly unnecessary chances with his life and limbs; chances which in no way add to his efficiency or his earnings. The maintenance of strict discipline in the shops, the adoption of salutary punitive measures and the firm elimination of the dangerous employe is all that can be done, in addition to a campaign of education throughout the plant.

Accident is caused at many machine parts which are necessarily exposed near the operator, and with which he would never come into dangerous contact but for unsuitable or neglected clothing. The ragged sleeve ends, loose ties and open jackets of untidy machinists have again and again been wound upon seemingly trivial parts in motion and through the powerful effect of coil

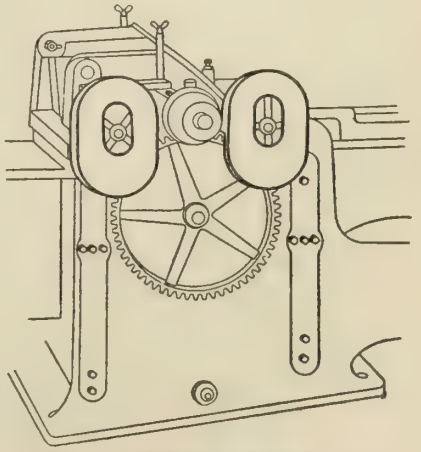

Fig. 3.—Properly Protected Gears.

friction have inflicted frightful and often fatal injuries.

Insufficient lighting is a cause of numerous accidents, particularly serious and fatal falls. A maximum of accidents occurs towards the close and beginning of each year, that is during November,

December and January, the months of minimum daylight. Fig. 1 shows the seasonal distribution for three successive years of about 700 deaths annually from industrial accidents, which were reported with other injuries from an area embracing 80,000 plants of varying extents.

The intensity of artificial lighting at the cutting point of tools, and on very limited machine tool or bench areas is

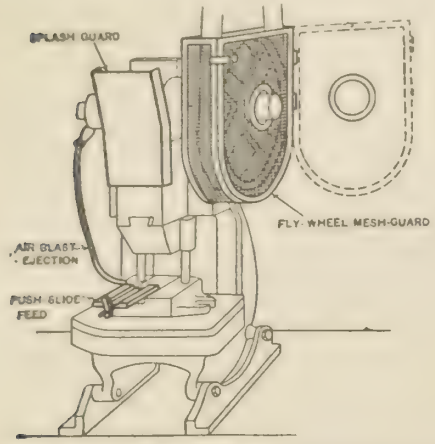

Fig. 4 Good Wire Screen Protection for Driving Wheel.

frequently far above actual requirements and a source of much physical discomfort, while all around the operator a semi-darkness prevails which has a blinding effect and is a source of danger.

The Possibilities of Safeguarding.

The absence of safeguards closely concerns the mechanical engineer, who holds the possibilities largely in his own hands. In many cases of injuries to operatives caused by the absence of a passible safeguard, it will be found that it has been removed, or rendered ineffective by the employe for lack of supervision in such matters or that protection has never been provided. Safeguarding absent at one machine is sometimes actually afforded elsewhere under the same roof and the accident is due to the operation of the principle that what is permitted to be everybody's or anybody's business is in daily life nobody's business. The safety engineering of no plant should be left to the haphazard initiative of a number of individuals.

Consideration of what the mechanical engineer can contribute to this end naturally falls into two divisions: (a) the efficient safeguarding which he may design as an integral part of the machine tools and other apparatus and (b) the safeguarding which he may later devise and supply as the mechanical engineer or executive of plants using power apparatus and other equipment capable of inflicting injury.

Machine Builder and Safeguards.

Numerous instances might be cited of the vague notion expressed in some current machine designs that anything which looks like a cover for a part of a machine necessarily constitutes in daily service an efficient safeguard; sometimes no regard is paid to the actual direction of rotation or to reversal of motion or to the necessity in using the tool for frequently removing a clumsy cover which is as likely as not to be left off permanently. The real points of danger in daily operation need to be studied before a satisfactory protection can be provided.

Punches and Presses.

Punch and press machinery probably ranks next to wood-working tools in frequency of accident, though usually the operative escapes with less serious injury. The mechanical engineer cannot be too careful in seeing that these tools are in good repair, particularly the actuating gears. Automatic roll-feeds, sub-presses, magazine, hopper, gravity

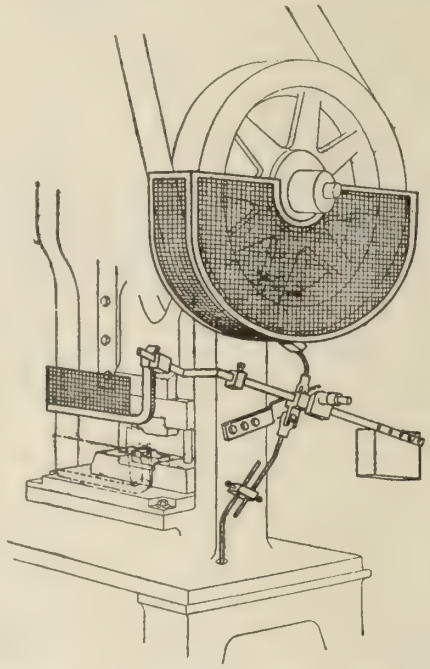

Fig. 5.—An Automatic Screen Guard for Press.

slides, and push slides feeds, have done a good deal to eliminate the dangers of feeding such presses by hand but much work already blanked must still be handled in this way in subsequent punching and pressing operations.

The increasing use of compressed air in mechanical industries permits of light pieces being blown off the die at the end of the operation by a cam-operated blast properly directed and timed, Fig. 41. The ordinary spring ejector serves the same purpose for heavier work. Yet there are many punches and presses running to-day without the efficient safeguards here illustrated and even where they are to be found the principles are not carried out consistently at all necessary places.

Fig. 4 is an example of a convenient flywheel guard, ordinarily locked in position, which the author arranged for a large series of small bench power presses worked by females. Provision is made in it for the tool setter having ready access for moving the flywheel by hand without detachment of the safeguard and resulting failure to replace it. The work in this machine is fed in by a push-slide and removed by a cam-actuated air blast. Fig. 5 shows a form of press guard, which is timed to descend upon the operator's finger, if in a position of danger, and secure their withdrawal before an accident occurs.

Emery wheels, grindstones and other abrasive tools when over-speeded or when strained or shocked while in motion within the limits prescribed by the maker, sometimes burst with great violence and spread death and serious injury in the path of their flight. Various methods for confining the wheel fragments to the machine casing or at least rendering their velocity harmless have been worked out and some of these are illustrated in Fig. 6. In all of them ample side clearance between the wheel and its casing is a primary requisite.

Durability and Identification of Safeguards.

Safeguards, where at all possible, should be constructed of metal to secure durability. Reinforced steel mesh work is preferred for all but the heaviest machinery. It is superior to guards of opaque material since it permits easy inspection without detaching the safeguard and interferes as little as possible with lighting conditions. In steel mills, foundries and heavy work plants of various descriptions, where the wear and tear of equipment is very great, no-

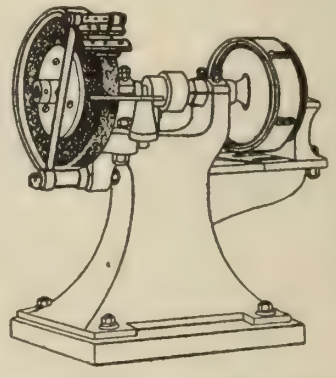

Fig. 6.—Safety Adjustable Hoods for Disc and Face Grinders.

thing but strong castings or steel plate work should be used for the majority of the guards. It is a good practice to have all safeguards readily distinguished by painting the body of them vermillion and the reinforced edges black. This allows executives to detect at a glance in going through the shops, a displaced or defective guard, such parts being often small in area, in inconspicuous places, and liable to be overlooked.

Twist Drill and Other Internal Cutting Tool Practice--II

By K. Campbell

Modern Shop Practice has Developed Various Types of Twist Drills, Reamers, Counter-Bores, Etc., Greatly Increasing the Capacity of the Machine Using These Small Tools. The Breakage of Tangs Formerly Caused a Great Loss, But This has Now Been Eliminated by Modern Practice. Part I Appeared in the March Issue and Dealt with Drilling in General, Some Types of Drills, Sharpening, Speeds, Shanks, Tangs, Etc. This Article Gives Some Additional Information on Drills, Drill Grinders, Etc., and also Deals with Reamers, Counterbores, Etc., the Information Being Secured from Manufacturers, from Various Technical Publications, etc., May Therefore be Relied upon as Accurate.

FOR accurate drilling the grinding is very important as was pointed out in the March issue. With a view to obtaining a true cutting edge, machines have been placed on the market to secure this desired end. Figs. 15 and 16 show the form given to the lip of a drill by the Sellers grinding machine. The axis y-y of the cone is inclined to the axis b-b of the drill, and also lies in a different plane as shown in Fig. 16, thus giving the cutting edge of the drill the necessary clearance, which increases towards the drill point as will be readily seen. The shape of the end of the drill-lip is part of the surface of a right cone, the axis of which will be coincident with the cone to be ground. If we assume the cone shown in Figs. 15 and 16 to be a grinding wheel revolving about the axis y-y with the drill point held against it as shown, the surface of one lip will evidently be ground to the desired conical form. To produce this shape of drill-lip in practice, it is not necessary to grind in the manner just described ; that is, by holding the drill against a conical abrading wheel, which revolves. An emery wheel having a flat surface, tangent to the theoretical cone required, will grind the same shape if the drill be made to swing about the axis of the cone.

Twist Drill Grinding Gauge.

In the March issue of Canadian Machinery a drill gauge was shown and its usefulness pointed out. In a recent issue of the American Machinist a simple gauge which may be easily made, was shown. The gauge is made of three pieces, two of which are riveted together and form the stock. See Fig. 17. The stock is machined at its upper end, prior to the riveting, to form a slide for the actual angle gage ; it also has a V machined along its straight side. The drill to be tested is laid in this V and the angle gage is then adjusted until its two angular edges make contact with the cutting edges of the drill, as it lies in the stock, then the drill is rotated a half turn ; if now, the two cutting edges make contact with the angular edges of the gage it will at once be obvious that its two cutting edges are of the same length as each other, and that the angle at which they are inclined to the axis of the drill is the same for one edge as for the other. It follows from this, that the point of the drill will be central with its axis.

High Speed Drill Speeds and Feeds.

Fig. 10 in the March issue for carbon drills. Fig. 18 and 19 are for high speed drills and are taken from a paper read before the Institution of Mechanical Engineers of Great Britain. Fig. 18 gives the r.p.m., feed per revolution, cu. ins. removed per min., and h.p. when

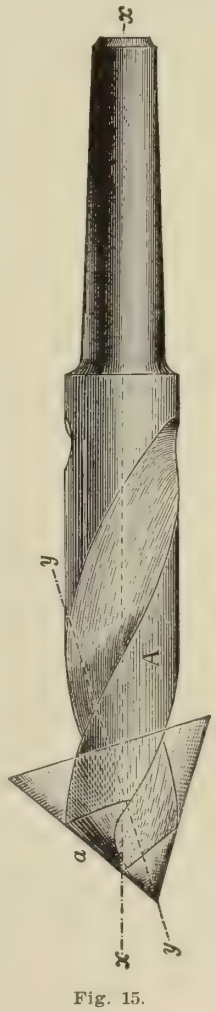

Fig. 15.

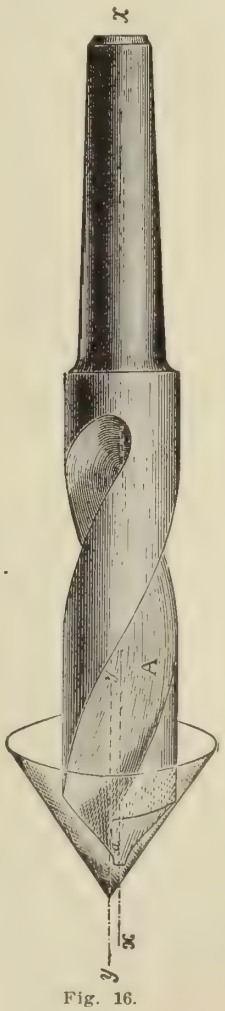

Fig. 16.

drilling cast iron with high speed steel drills. Fig. 19 shows the same items when drilling medium hard steel with high speed steel drills.

These two tables are recommended by drill makers for ordinary shop use. There is no general agreement among the makers of high speed twist drills as to what the cutting speed should be for ordinary shop practice. Some decrease the speed with the increase of diameter of drill, some recommend the reverse, but most makers advise a constant periphery speed throughout.

Special Drills.

Fig. 20 shows an end mill with centre cut. They are made to run right and left with a Morse taper shank. These end mills are useful where it is desired to cut into the work with the end of the mill and then move along as in cams, grooves, etc., as the teeth are sharp on the inside, and thus cut a path out from the first entering point. They are also useful in taking heavy cuts, especially in cast iron. They are made from $\frac{1}{2}$ in. to $1\frac{1}{2}$ ins. in diameter and to cut from 1 in. to $2\frac{1}{4}$ ins. in depth.

Fig. 21 shows some cored holes in flat cast iron plates to be reamed. For this it is best to use a short twist drill ground on the sides gradually tapering to the point. When reaming holes in structural shapes which are similar to Fig. 21 after punching, a three-fluted reaming drill is used.

Steel Reamers.

Reamers are now being made with high speed blades so that for this class of cutting tool the advantage of the increased work is obtained without the disadvantage of high cost. To get a solid reamer, high speed steel blades have been brazed to a soft body in the manner illustrated by stages in Fig. 22. A body of soft steel is grooved and fluted and bars of the required steel are then inserted in the grooves and secured by indenting the metal forming the adjacent front wall in a series of light indentations, a, by means of a punch, and forcing the blades into the bottom of the grooves, after such identations have been formed, by placing in a vise, or by other means. These indentations have the effect of forcing the metal into very close contact with the blade, retaining the blade in position by the frictional contact of the metal of the shank with the blade. Binding wires are then placed around the tool to retain the blades during the brazing and hardening oper-

ation. After the tool has been heated to the proper point for hardening the steel, and the whole has been treated with a proper flux and solder, it is cooled so as to secure the proper hardening of the steel and the setting of the spelter to form a bond between the blades and the head. When the tool is heated with the retaining wires around it the wires will become expanded, so that they do not serve to retain the blades very securely during the heating

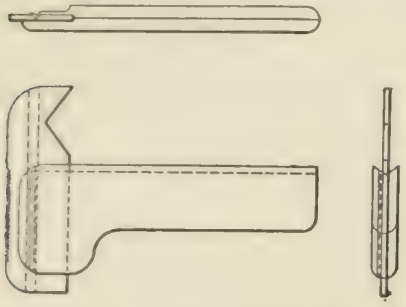

Fig. 17.—Twist Drill Grinding Gauge.

and brazing process; but when the tool is cooled the binding wires will be cooled first and will consequently sharply contract and force the blades to the

Fig. 20.—Left Hand End Mill.

bottom of their seats before the spelter sets. The tool is then cleaned and ground to finish.

Reamer Feeds and Speeds.

It is always advisable not to have any more material than possible to be removed by a reamer. For general work the amounts given in the following list taken from "Machinery," will give good results ranging in diameter from $\frac{1}{8}$ to $\frac{3}{8}$ inch. For reamers over $\frac{3}{8}$ inch diameter, a drill 1-64 inch less in diameter is

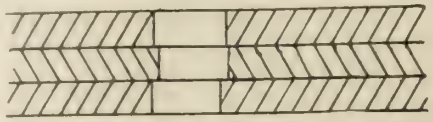

Fig. 21. Holes to be Reamed for Straight Bolting.

generally used, and this would leave from 0.012 to 0.015 inch to remove on the diameter, as it is obvious that a drill will cut slightly larger than its nominal size.

Diameter of reamer in inches.	Diameter of hole previous to reaming in inches.
$\frac{1}{8}$	0.120
3-16	0.182
$\frac{1}{4}$	0.242
5-16	0.302
$\frac{3}{8}$	0.368

There are various reasons for the inefficient working of a reamer, some of which are the following:

1. Chattering, which results when the teeth are evenly spaced or of an equal number.

2. Chips clinging to the teeth, which action results when high periphery velocities are used and insufficient clearance given.

3. Expanding and contracting of the hole which is caused by too great a feed and insufficient clearance on the cutting edges.

4. Enlarged and tapered hole due to holding the reamer rigid instead of floating.

The following is a table of feeds taken from "Machinery" and is for

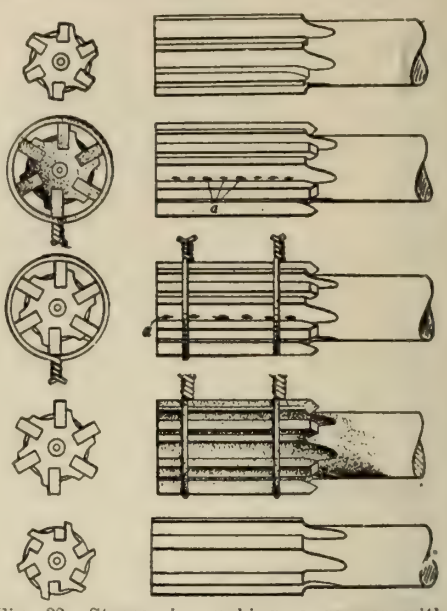

Fig. 22.—Stages in making a reamer with brazed high-speed steel blades.

reamers made from high-speed and carbon steel.

Fig. 19.—R.P.M., feed per revolution, cu. ins., removed per minute and h.p. when drilling medium hard steel with high-speed steel drills.

Counterbores.

Dealing with counterbores, Douglas T. Hamilton writes that the surface speed at which a counterbore can be worked is slightly less than the surface speed used for drilling. The surface speeds given below are recommended for counterbores made from carbon and high speed steel.

Speeds From Counterbores Made From Carbon Steel.

Material	Surface speed in feet per minute
Brass (ordinary quality) ...	150-160
Gun screw iron	50-60
Norway iron and machine steel	40-50
Drill rod and tool steel	30-35

Speeds for Counterbores Made From High-speed Steel.

Material	Surface speed in feet per minute
Brass (ordinary quality)	180-200
Gun screw iron	80-90
Norway iron and machine steel	70-80
Drill rod and tool steel	45-50

The rate of feed at which the counterbore should be operated, depends on the nature of the work, to what depth it must penetrate, material being cut, number of cutting edges, etc., and there is no definite rule as to the exact feed to use.

INDUSTRIAL TRAINING IN ONTARIO.

At the recent session of the Ontario Legislature Dr. Pyne, introduced a bill which allows any urban school board to establish industrial schools, special industrial schools, technical high schools, co-operative and industrial schools, schools for instruction in fine and applied arts, industrial and technical and evening art schools. The regulations for the schools are to be provided by the Department of Education in the same way as in the case of a High school, and, subject to those regulations, the minister is to apportion all sums of money appropriated by the Legislature for the establishment and maintenance of such schools. The high school grant at present is apportioned according to the number of pupils, the equipment, and the qualifications of the teachers.

General industrial schools are those in which to the regular course there are added special classes calculated to prepare pupils for industrial life. Special industrial schools are those providing instruction in theoretical and practical work of particular trades carried on in the district where the school is situated. Co-operative schools are those in which an apprenticeship system is combined with the school course.

It is provided in the bill that every technical school, whether at present in operation or established hereafter, is to be under the management of a committee of twelve, six from the Board of Education, three persons not members of that board who are engaged as employes in manufacturing or other industries carried on in the district, and three employers of labor. This is to be known as the Advisory Industrial Committee. Where there is more than one school in the district there may be one or more committees, as the board desires. The committee is to be appointed by the Board of Education, on nomination of the chairman. This committee, subject to the Minister of Education and the Board of Education, will have power to provide buildings for industrial classes, to establish classes in other school buildings and to prescribe the course of study. The committee will also have power to engage teachers, fix their salaries, to asrange the finances of the school, and to do anything else necessary for its maintenance.

The Department of Education, by regulation will provide for the qualification of teachers, the course of study, the character of school sites and equipment, and the maximum and minimum fees which may be charged.

The Development of the Bertram Convertible Planer

The Designing of a Planer Body to Which Any Attachment Such as Right Angle or Parallel belt Drive or Motor Drive May be Applied, Means a Great Economy to the User Who Has Specified a Certain Drive. A Delivery May be Made Practically at Once Where Formerly Several Weeks Elapsed Between the Ordering and the Delivery of the Planer.

OF the long list of machine tools probably the planer has given more trouble to designer and user than any other machines. It was designed for one drive and a user had to accommodate himself to that drive whether it suited his shop or not. Later when devices and driving mechanisms were designed a user could get what he wanted if he waited long enough on delivery. This was often annoying for he wished to make immediate use of the planer.

The latest development in the design of a metal working planing machine, however, is a radical departure from the early system. The John Bertram & Sons Co., Dundas, Ont., have designed a planing machine body to which right angle belt, parallel belt or motor drive may be attached according to the specifications. The planer bodies and the various drives are manufactured for stock so that when an order for a planer is received, the necessary equipment is fastened to the standard body, and it is shipped complete in a few hours or a day or two at most, where previously several weeks elapsed to the great annoyance of the buyer.

Four Belt Right-Angle Drive.

Fig. 1 shows a 36 in. x 36 in. heavy type iron planing machine with four belt right angle drive. It admits 37 ins. between the housing and 37 ins. under the crossrail. The standard length of the table is 10 ft. independent of pockets.

There are four cutting heads, two on the crossrail and a side head on each standard. The heads on the crossrail have swivelling saddles and independent cross, down and angular feeds.

Power is transmitted to the table through a train of accurately cut gears. The crossrail is raised and lowered by power.

The table is 33 ins. wide and has three T slots the entire length and six rows of holes for securing the work. The V's have a bearing surface of 5½ ins. each and are 20 ins. from centre to centre, fitted with oil pockets for lubricating the table. The bed of the planer is 20 ins. deep and 26 ins. through the body, and the uprights have a width of face of 8¼ ins.

The planer is equipped with Bertram patent four belt drive. The driving pulleys are 26 ins. in diameter for 2½ in. belts giving the same pull as one 5 in. driving belt and one 5 in. return belt but quicker reverse. The reverse pulleys are 20 in. diameter using the same belt width.

Fig. 2 shows a rear view of 36 in. x 36 in. iron planer with four heads, driven through countershaft with right angle new type four belt drive.

The V-angle of the planer is flattened and the inside lip takes up the side shock thus preventing the planer surface plate being pushed out of the V's.

Feed Arrangement.

The feed arrangement is shown in Fig. 3. By a reference to this illustration it will be seen that studs fit in slide that fits in T slots. Tools can therefore come

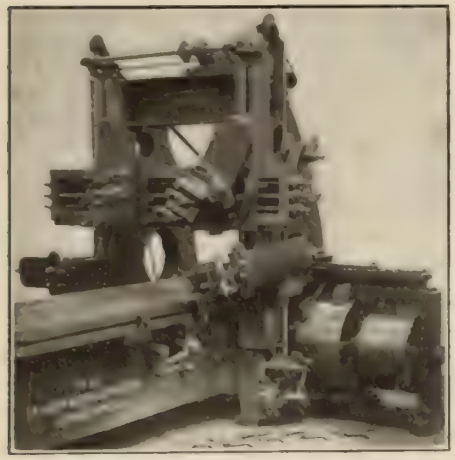

Fig. 1.—Front View, Four Wheel Right Angle Drive.

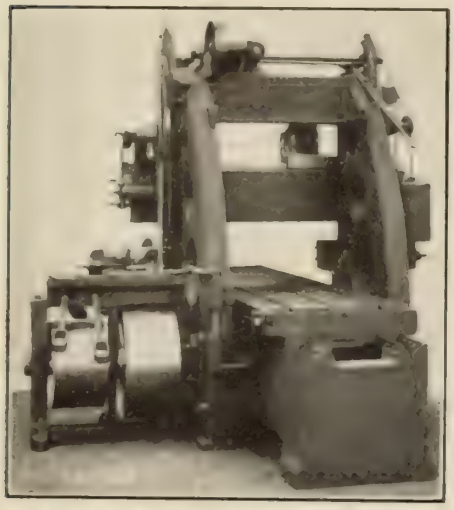

Fig. 2.—Back View, Four Wheel Right Angle Drive.

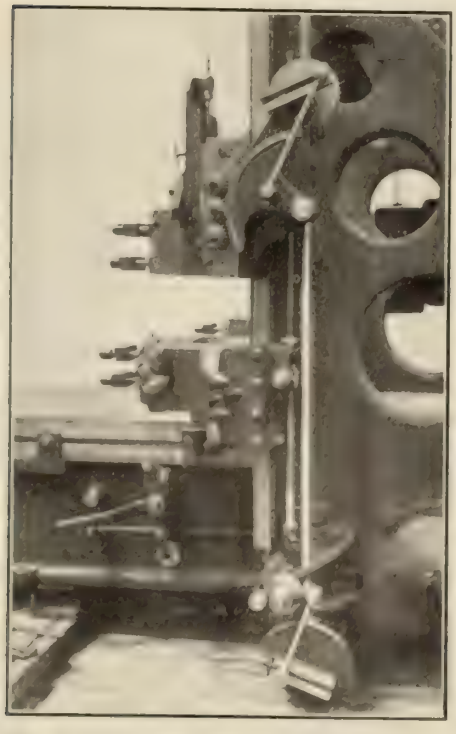

Fig. 3.—Feed Arrangement, Bertram Convertible Planer

together and are right and left. This is a new and good feature on Bertram planers.

Parallel Drive.

By changing the attachment the planer may be converted into a parallel drive. Fig. 4 is a front view of a 36 in. x 36 in. iron planer with four cutting heads, belt driven through countershaft, with parallel new type four belt drive. The gears which run in oil, are covering thus effectively preventing any accident from this part of the mechanism.

Fig. 5 shows a rear view of a 36 in. x 36 in. iron planer with four cutting

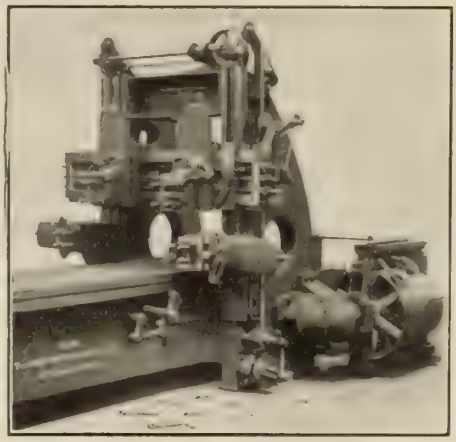

Fig. 4.—Front View Four Belt Parallel Drive.

heads, belt driven through a countershaft, with parallel new type four belt drive.

Motor Drive.

By the addition of a casting to the top of the standards, the planer may be equipped for motor drive. Fig. 6 shows a 36 in. x 36 in. iron planer with right angle drive by motor. To operate the planer a 15 h.p. constant speed motor running at 1200 r.p.m. is required.

A rear view of this planer equipped for motor drive is shown in Fig. 7.

At the annual meeting of the B. Greening Wire Co., Hamilton, N. S. Braden of the Canadian Westinghouse was elected a director.

George J. Duffey, formerly master mechanic at the Michigan Central Railway shops in St. Thomas, has been appointed master mechanic of the Lake Erie & Western Railway, with headquarters at Lima, Ohio, succeeding F. H. Regan, resigned.

J. Hay, of London, has been appointed locomotive foreman at the Sarnia tunnel, G. T. R., in place of W. H. Towne, resigned. Mr. Hay's place is taken by J. R. Leckie, of Palmerston. J. A. Waldron, machinist at Lindsay, has been appointed G. T. R. locomotive foreman at Palmerston.

Is Factory Location Immaterial, If Product Unexcelled?

By Penstock

Someone Has Given Expression to the Statement that "if a Man Can Write a Better Book, Preach a better Sermon or Make a Better Mouse Trap Than His Neighbor, Although he Build his House in the Woods, The World will Make a Beaten Path to His Door." We are Rather Doubtful of the World Becoming so Demonstrative.

IF the preamble be true, reformation involving revolution in our civilization should be immediately consummated, for our upbringing, education, business training, social and recreative methods and pursuits are one and all more or less at variance with the expressed eventuality.

Contrary to Reason and Intelligence.

Is it, however, true to fact? Our answer that it is not, admits of no possibility of serious questioning, constituted as we find ourselves. The writing of a better book, whatever that may mean, by a man who elects to bury himself in the bush, is together with his book considered of infinitely less moment than a remedy for overcrowded street cars. For one thing he appeals to a much smaller community, and for another he and his book are less of the nature of a public utility and necessity.

The preaching of a better sermon by a man in the city crowd, and its response, is surely indictment enough of the ridiculousness of its efficacy in starting a trek to the woods.

Forgetting for the moment that a large proportion of our fellows even in Christian countries have ceased to be enamoured with sermons of any quality, it seems highly improbable that the "call of the wild" would appeal to the wearers of silk hats, Prince Albert coats, dressmaking and millinery creations as effectively as religious appearance in what is known as a fashionable city church with a hum-drum preacher.

The discovery of gold, silver or other precious metal precipitates a rush to the field. Did it ever occur to you how microscopic is the percentage entrapped in its lure?

The majority of us theorize that the doctor should come to his patient, and in actual practice in every condition or circumstance he eventually does. With his coming a cure is made more certain; of the ultimate output of the mine, people several thousand miles away participate to the largest extent; of sermons and books, comfort and leisure in which to listen and digest are elementary considerations of sound philosophy.

The Manufacturing View.

The mouse trap feature brings us into manufacturing, and there as in these other spheres, the world does not see warranty for making a beaten path to a factory door.

We live in a progressive age; the mouse trap in the limelight to-day, may be junk to-morrow even where mice are a nuisance. What hope then is there for the backwoods manufacturer of such a commodity?

An army dare not move too far from its supplies base else its effectiveness as a fighting and conquering machine will be seriously impaired. The manufacturer for the same reason may not locate his factory just where personal vanity in his fleeting achievement of producing an unsurpassed utility, may dictate. A stern law of economics over-rules and penalizes his imprudence of its non-observance should he take any such step.

Sufficient has been said to show the utter worthlessness of a too literal application of the preamble, and confirms our pre-determined conclusion that "factory location is material, irrespective of superlative product."

Produce a Missionary.

Having so satisfied ourselves, does superior and effective location then, backed by the best product, warrant the assumption that the world will now beat paths from its circumference to our centre af effort? We trow not. The world as generally known, treats with a generous degree of studied indifference, most of the happenings and innovations that it meets accidentally or otherwise, as it gets around. To make it take notice, arrest and hold its attention requires personally persuasive, sympathetic and systematic effort additional.

The manufacturer must make beaten paths radiate from his centre to all points of the world's surface and circumference, that his product is designed to reach. By display, mail, representation (local or itinerant), and advertising, must he "ancient mariner like" arrest and deliver his message to those he reckons as being needful of his service.

Sitting at his desk will not avail unless he is unceasingly regulating and disseminating realistic information of what he manufactures and sells.

Variety of Appeal Necessary.

All manner of ingenuity must be displayed as all manner of being has to be approached. What appeals to one by sight may be unseen by another, and it is a matter of common knowledge that this blindness is widespread.

One man sees in the completed machine, only the skilled designer and mechanic; another man sees a tool by which he can produce a cheaper and better grade of flour it may be.

The field to be tapped is so complex that the methods already referred to are all necessary to a lesser or greater extent.

Sincere Effective Advertising.

Manufacturers are fully realizing this demand to-day, and are backing it up by sincerity of statement. In this they are ably supported by trade journals.

Advertising in these to-day is not a catch penny question. The page of such a paper is an equally well dressed window to that of a departmental store, gives point to every special feature and appeals to the purse like bargain day.

We are convinced that clean advertising concentrated as regards mediums used and extended in quantity, carries the palm as the pioneer in beating the path out from your factory door, and the eliminator of that hardship and inconvenience which the world sees in its suggested initiative, and from which it shrinks.

Effective and systematic advertising is more than half the battle in securing your market, and followed up by direct personal assurance from and by you in your prospective customer's sanctum instead of in yours, cannot fail to win out entirely.

Every doctrine of political economy and philosophy warrants us in stating that present methods do conspire to results, and that a much distorted conception of how the beings of this old world are constituted, is responsible for this book, sermon and mouse-trap theory.

Need of Waking Up.

Consumers generally busy themselves with a host of questions more or less unbeneficial to their best interests and as a consequence, lose sight of this latter unless more extraordinary means than this "call of the wild" are adopted.

The increasing strenuousness of living will always tend to and gradually smother out this call, while that of the others will of necessity become louder. Mens' self-forgetfulness will continue to build a barrier to be assailed in addition to a path to be beaten and kept open. The exercise of yet undemonstrated genius will be required, and the veriest hint of a pilgrimage to the bush to get what we want, will spell failure at the outset.

THE WHEEL MUST BE "TRUED."

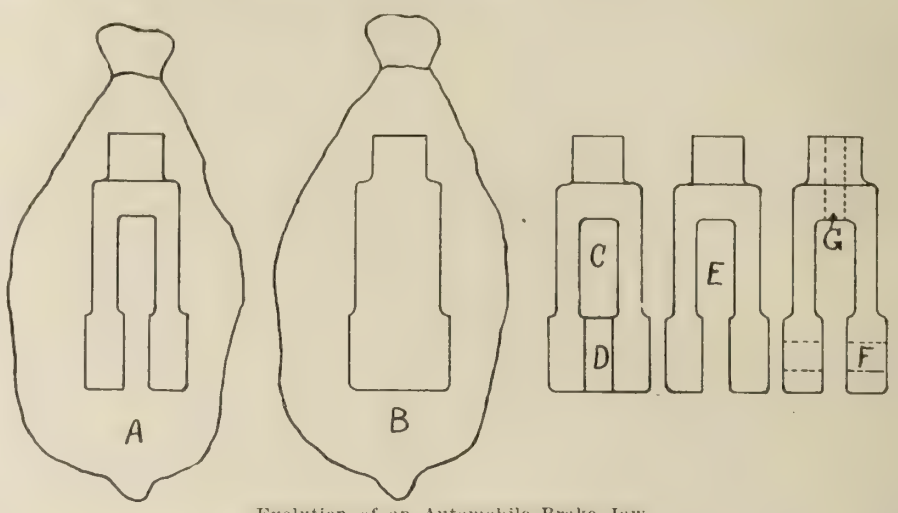
In cylindrical grinding we can never grind perfect work with an imperfect wheel. It is important that the operator shall realize that the more perfect and smooth his wheel, the more perfect and smooth his work will be, when making the light finish cuts. We make little or no attempt to grind smooth when making the roughing cuts. During these cuts, when the wheel is cutting heavy, the surface will be coarse and sometimes "chattered," owing to rapid work and deep cut, but this can do no harm if not too deep to "finish out." Between the roughing and finishing cuts the grinding wheel must be "trued" in order to obtain round, smooth work, and the lustre of the surface depends upon the lustre we produce on the wheel face when truing, also on the lightness of the cut we take, as well as on the speed at which we revolve the work when finishing. We evolve the work slower when finishing than when roughing.

When using a Norton Machine truing does not mean "sharpening" the wheel; but it does mean "dulling" the face in order to obtain a finish. It also means that when "truing," we perfect the wheel, viz., we make a perfect cylinder of the wheel in order to grind a perfect cylinder with it.—From a talk by C. H. Norton of Norton Grinding Co.

WIRE GUARDS.

The accompanying illustrations show two wire protectors which are very efficient. One shows a floor guard protecting gears and the other a wall guard protecting the switchboard. The one around the switchboard may be locked and thus prevent any tampering with it.

These guards are manufactured by the Canada Wire Goods Mfg. Co., Hamilton, and the two photographs shown were taken in their factory. Besides manufacturing guards for protecting machinery they make a line of incandescent light and window guards, etc.



BRAKE JAW FORGING.

By K. L. K.

One of the interesting processes in the modern automobile plant is that of forging. In the works of the Canada Cycle & Motor Co., Toronto, various parts are evolved by a few simple operations. The equipment consists of a large power hammer and the necessary dies.

The die block parts in the centre line, the lower half being fastened to the centre line and the upper half to the ram of the hammer. The piece of stock from which the brake jaw shown herewith is made and which is used to illustrate the method of procedure, is heated to a good forging temperature. The upper half of the die block is used as a hammer to strike the hot metal a series of blows and thus force the hot metal to take the shape of the die block, filling the recesses in both halves and producing the forging shown at A.

Considerable clearance is allowed so that the metal can easily fill the recesses. A piece of stock is used large enough to more than fill them as will be seen by the metal wings on the brake jaw at A, which is the condition of the forging at the end of the first operation. In fact this is the end of the forging, the second being the trimming operation.

Evolution of an Automobile Brake Jaw.

To trim the brake jaw the anvil half of the trimming die block is hollow the shape of the brake jaw, while the ram is the shape of the jaw and exactly fits the anvil. The result is that the brake jaw is pushed through leaving the wing on the anvil. This operation is accomplished on a press.

The third is also done in this manner. The anvil die block consists of a hollow die block the shape of the brake jaw with ram or punch the shape of the centre at C. In the fourth operation the part D is removed leaving the brake jaw as at E. It is then drilled at F and G, thus completing the operation.

Boiler Design, Construction, Operation, Repairing and Inspection*

By H. S. Jeffery

The Various Points in Connection With Boiler Practice Will be Clearly Taken up in This Series. The First Article Deals With the Boiler Shell, Including Repairing, Factor of Safety, Hydrostatic Test and Number of Courses. The Series Will be a Complete Text Book on the Subject of Boilers, and They Should be Preserved for Reference.

The Rivet Pitch.

(12) The rivet pitch is a matter which must be decided first, and then the other parts arranged. The pitch must not be so excessive as to permit the plates to spring between the rivets, and which will cause the rivets and seams to leak. No stated pitch can be given for a certain thickness of plate, or for a certain size rivet—the best that can be done is to set a maximum pitch for different types of riveted joints with different thickness of plate, and then use whatever size rivet as will permit the riveted joint to be properly designed.

The following formula gives the maximum pitch:

$$(C \times T) + 1\ 5\text{-}8 = P$$

Where:

C=Constant applicable from Table 1.

T=Thickness of plate in inches.

P=Pitch in inches. (See note*.)

TABLE 1.

Rows of Rivets..	1	2	3	4
C. for Lap Joints	1.31	2.62	3.47	4.14
Constant for Double Butt Strap joints	1.75	3.50	4.63	5.52

Example. With a single riveted lap joint, plate 3-8 inch, what is the maximum pitch?

Solution:

(1.31 x .375) + 1 5-8=2.116 inches, or 2 1-8 inches.

Double-Strapped Butt Joints.

(13) The majority of boilers are now constructed with double-strapped butt joints for the longitudinal seam. The lap joint does not permit making the boiler as round as does the butt joint, nor does the lap joint make it possible to make the efficiency of the longitudinal seam as great as when the double-strapped butt joint is employed.

In Fig. 17 is shown a single riveted double strapped butt joint. It is single riveted as the shearing of either of the rows of rivets will permit the sheets to separate, though the rivets are in double shear.

Referring back to the calculations of the single riveted lap joint, it will be seen that the efficiency of the net section of plate is 62.5 per cent., while the rivet efficiency is 44 per cent. For the sake of illustrating it will be assumed

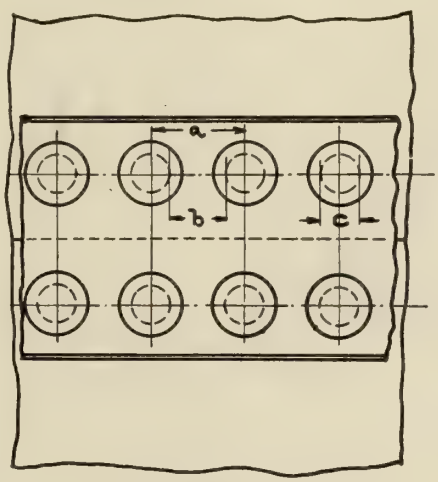

Fig. 17.

that the letters a, b and c, Fig. 17, represent the same values as in Fig. 12, which, of course, will mean that the efficiency of the net section of plate of Fig. 17 is 62.5 per cent.

But, the rivets being in double shear, increases their shearing strength, and thus their strength must be found and compared to the strength of the solid plate in order to determine the efficiency of the rivets. The shearing strength of the steel rivet in single shear was stated to be 45,000 pounds per square inch and that a rivet in double shear was 1.85 times 45,000 pounds, making 83,250 pounds.

Then substituting values, the efficiency of the rivet is:

$$\frac{.44179 \times 1 \times 83{,}250}{60{,}000 \times .375 \times 2} = 81.7 \text{ per cent.}$$

Attention is now directed to the fact that with the single riveted lap joint the rivet efficiency is 44 per cent., while with the single riveted double strapped butt joint (same size and pitch of rivets in both instances) it is 81.7 per cent. The efficiency of the net section of plate remains of course, 62.5 per cent. in both instances.

With the single riveted lap joint the efficiency of the plate exceeded the rivet efficiency, it being pointed out that to use a larger rivet would increase the rivet efficiency and likewise reduce the efficiency of the net section of plate, which would tend to equalize matters.

With the single riveted double strapped butt joint, the rivet efficiency exceeds the plate efficiency, thus indicating that the pitch might be increased so as to increase the efficiency of the plate and reduce the rivet efficiency.

Whether or not this course would be advisable relates only to the question as to pitching the rivets so as to make the joint steam-tight. The calculations indicate that the pitch can be increased to some extent, and now by referring to Table 1 and the formula in connection therewith this question can be decided.

Example. With a single riveted double strapped butt joint, plate 3-8 inch, what is the maximum pitch?

Solution:

(1.75 x .375) × 1 5-8=2.28 inches.

As the pitch used in the calculations was 2 inches, it will be seen that this is below the maximum pitch allowed, and, accordingly the pitch can be increased, thus causing the efficiency of the net section of plate to increase while the rivet efficiency will decrease. It is advisable, however, to keep the rivet efficiency above the plate efficiency to some extent, and to do this may make it impossible to increase the rivet pitch to the maximum pitch.

Wm. Edestrand, of the Dain Mfg. Co., Dain City, has been appointed manager of the Welland Machine & Foundry Co., Welland.

Some concerns in certain lines of manufacture requiring many comparatively simple and cheap special machines, make a practice of purchasing second-hand machine tools. The headstocks and slides are worked over at small cost so as to adapt them to the desired purpose. Many special machines are in use in a certain factory, built up from regular machine tools at very low cost, the functions of which are quite different from those for which the machines were originally designed.—Ex.

---

*Note.—With a double-riveted double-strapped joint, the constant from Table 1 is 3.50, while with the double-riveted double-strapped joint the constant is 1.75. This has only reference to the pitch of rivets in double shear. Thus the pitch of rivets for the inner row of the triple-riveted double-strapped joint will have the same constant, 350, as used for the double-riveted double-strapped butt joint.

Mechanical Drawing and Sketching for Machinists*

By B. P.

A Series of Progressive Lessons Designed to Familiarize Mechanics With the Use of the Apparatus Necessary to Make Simple Drawings, to Encourage them to Realize How Important a Factor it is of Their Equipment, as Well as Being a Profitable Pastime.

SET squares or triangles 30-60 degrees and 45 degrees, Fig. 7, with sides 8 and six inches long respectively, are suitable for most services and may be had in maple, cherry or mahogany with ebony edge, or in vulcanite, celluloid or other transparent composition. The latter are much used with open centres as illustrated.

The pencil has been already referred to, the only additional remark called for in its choice being its hexagon shape requirement. As such, it serves the double purpose of giving a better grip between the fingers when in use and has little inclination to roll off the sloped drawing board when not in use.

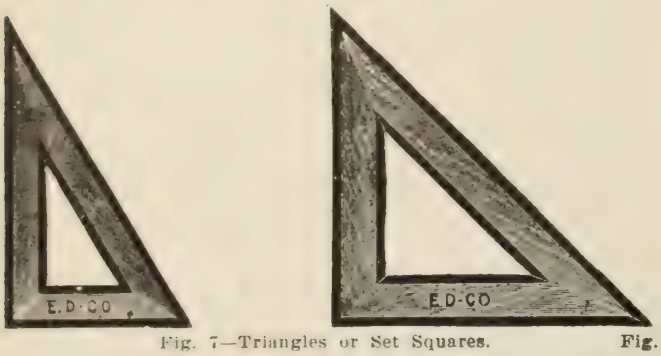

Fig. 7—Triangles or Set Squares.

Fig. 8—Drawing Pencil Points.

The pencil should be sharpened to a chisel point, Fig. 8, by means of which in the operation of drawing a straight line, the edge of the lead is kept close against the edge of the tee square or triangle.

Horizontal lines should be drawn from left to right and vertical lines from bottom to top of sheet. The tee square head should be held firmly against the board by the left hand and with the thumb pressure exerted on the blade as shown Fig. 9. The pencil also should be held firmly and vertically in the right hand, with the forearm and elbow kept well up from the drawing.

A very great help in keeping the otherwise unsupported pencil arm steady and ensuring against wavy lines, is to allow the little finger nail surface to touch the tee square lightly and allow it to slide along concurrently with the pencilling of the line. The arm movement in the drawing of straight lines should be as much as possible from the elbow.

Up to the present, only the apparatus for producing straight lines has been considered. Before passing to that pertaining to circles, parts of circles and curves, attention may be directed to pencil rubbers, or erasers for lines drawn in error or of excess length. Fig. 10 illustrates such an eraser, which should consist of soft fine grained rubber and be free from sand, glass or dirt, all of which tend to break or glaze the surface of the drawing sheet.

Compasses for drawing circles and parts of circles, vary in style, size, quality, purpose and price.

Those used for drawing large circles of varying diameter are generally 6 inches long. Such a set, Fig. 11, in addition to the needle and pencil points, includes a pen point and lengthening bar for circles in excess of those attainable by the self-contained instrument.

Small circles of varying diameter, and forming by far the major portion of compass work in the preparation of mechanical drawings, are best taken care of by the bow pen and pencil instruments. They are more conveniently manipulated, being lighter than the others and only 3½ to 4 inches long. Each tool as will be noted from the illustration Fig. 12, is complete in itself.

Fig. 11.

Spring bow compasses Fig. 13 are usually about 3 inches long and as their construction shows, are capable of accurate adjustment. They are most suitable in circumstances where a large num-

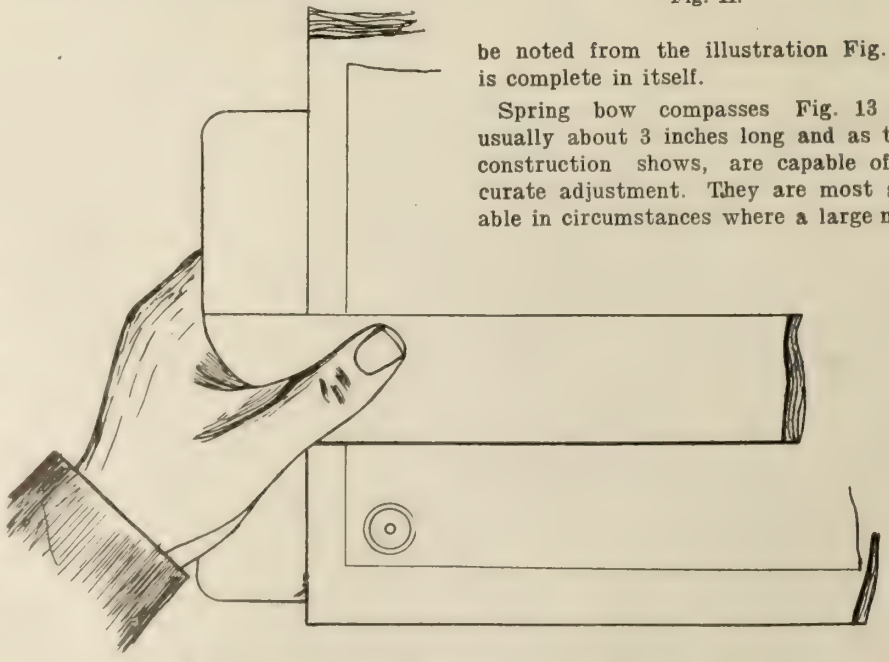

Fig 9—Application of T-square to Drawing Board.

*Third of a series of an Instruction Course. A lesson will be given each month

ber of circles of equal diameter are required.

The head joint of the two sets first described are an important feature to be attended to in making a selection for purchase. Double joints ensuring good lasting wearing surfaces should be their

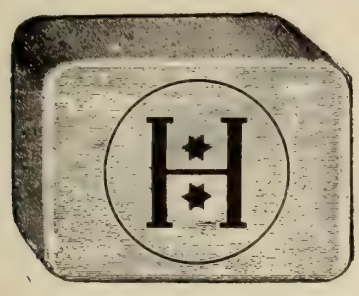

Fig. 10.

constructional detail. The needle, pen and pencil arms at the junction to the body should be similarly equipped.

The material of compasses generally, consists of German silver and good quality steel.

In purchasing instruments, those of the highest grade should be selected,

Fig. 12.

consistent of course with one's purse, if satisfactory work is to be comfortably achieved and usefulness of tools is to be guaranteed for 10 or 15 years under constant daily service.

The pencil for your compasses should be one grade softer than that of your drawing pencil.

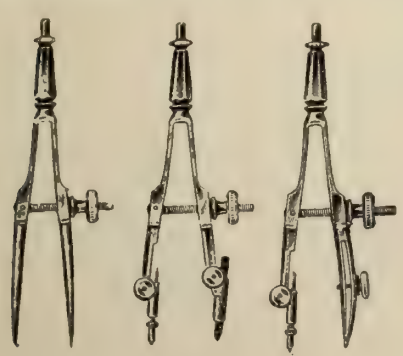

Fig. 13.

METAL LOCKER INSTALLATIONS.

By G. C. K

The value of the metal locker in the modern machine shop is being recognized. Formerly it was customary to drive a nail in the post and hang the coat or overalls, smock and towel any available place. The advantages over this method as well as over old wooden lockers, are many. For instance, wooden lockers are inflammable, badly ventilated, often uncleanly and full of vermin. They are thus very unsanitary whereas the metal lockers are safe and sanitary.

When a workman locks his coat, dinner pail, etc., in the locker of which he holds the key, he feels a sense of security, for each locker requires a different key. No employe can, therefore, unlock another's locker.

The use of the metal locker materially reduces insurance. There are no oil soaked smock and overalls lying around through the shop as these can be kept in the lockers.

Apart from the protective feature—affecting alike employers and employes—the educational value of the locker system in the cultivation of habits of order and self-respect is incalculable. If a workman is accustomed to putting away his own effects in the proper place, he will be more inclined to show similar care in putting away in their proper places tools and materials he has been using. Manufacturers, superintendents and foremen know what the care of machines, tools and materials, mean to the employer in dollars and cents.

Lockers are now being installed in a large number of the new plants but there are still a large number both of the new and older plants which should include them in their equipment. To the managers of these shops we would draw attention to the rule which was given due prominence in one of the workshops where the writer was employed, "A place for everything and everything in its place."

The adoption of the locker has been the natural outgrowth of modern business methods which has brought about conditions which make it absolutely essential that those things which assist in cleanliness, safety and dispatch shall be employed in up-to-date organizations.

In order to show that the lockers are growing in use the following list is appended:

Recent installations by the Geo. B. Meadows, Toronto, Wire, Iron and Brass Works Co., 479 Wellington street, west, Toronto, have been made; Somerville Brass Co., Berna Motor & Taxicabs, Ltd., Toronto; Northern Electric Co., Canadian Fairbanks, Montreal and Winnipeg; Brantford Carriage Works, Brantford; Robb Engineering Co., Amherst, N.S.; etc.

The Dennis Wire & Iron Works Co., London, Ont., have made installations in the plants of the International Acheson Graphite Co., Niagara Falls; Massey-Harris Co., Brantford; Tobin Arms Co., Woodstock; Lufkin Rule Co., Windsor; Kaministiquia Power Co., Fort William; N. T. R. shops, Winnipeg, etc.

The lockers shown in the half-tone were supplied by the Canada Wire Goods Mfg. Co., 182-186 King William street, Hamilton, who have made many important installations.

OBITUARY.

George A. Barnes, secretary of the Whitman & Barnes Mfg. Co., Akron, Ohio, was born at Cincinnati, Ohio, August 6th, 1857, died at Akron, Ohio, March 22, 1911. Mr. Barnes began his long service with the Whitman & Barnes Mfg. Co. at their Syracuse factory in 1876. In 1879 he was transferred to the Canton, Ohio, works of the company, remaining there as manager until 1895, when he removed to Akron, Ohio, at which place he resided until his death, with the exception of the years 1902 and 1904, when he was located at the Chicago offices of the company. At the time of his death, Mr. Barnes was Secretary of the company, a director, and member of the executive board. He is survived by a widow and one son, H. L. Barnes, who is superintendent of the Whitman & Barnes Mfg. Company's Chicago works.

A modern installation of lockers, made by the Canada Wire Goods Mfg. Co., Hamilton.

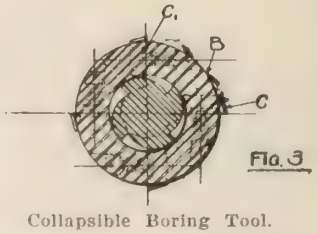
COLLAPSIBLE BORING TOOL.

By Jno A Bradley

A collapsible boring tool used for roughing and described in the following was designed for use in the manufacture of gasoline engines, but its adaptability to other lines may make this description of interest

Fig. 1 is side view, Fig. 2 an end view, while there is a sectional view taken through X X It consists of an inner arbor and cam shaft A, and outer arbor and tool holder B, cutters C of which there are twenty-four, and retaining screws D, a hand wheel E fastened to adjusting screw F, both of which are supported at one end by the bracket G and the cam shaft shifting lever H.



As previously mentioned this tool is used for roughing only. One end of the inner arbor and cam shaft A is inserted in the driving head, while the opposite end enters a pilot. When in operation the inner and outer arbors A and B rotate together, because of the adjusting screw F, one end of which is supported in the bracket G, fastened on the outer arbor B, while the other end

engages the cam shaft shifting lever nut L. The shifting lever H is fastened on arbor A.

The cutters C which are made a sliding fit in the outer arbor B are recessed as shown at C, to permit the end of the retaining screws D to enter, thus allowing the cutters to move in and out, a distance regulated by the length of the recess.

A very fine adjustment of the cutters is obtained by rotating the hand wheel E, the adjusting screw F having a fine pitch thread. The trunnion I supported in bracket G permits the adjusting mechanism angular movement

Collapsible Boring Tool.

The inner washer should be pressed or keyed on to prevent its revolving, and both should be relieved as shown in Fig. 2, so as to ensure a true bearing along the outer edge only. Compression rings of pulp or rubber should be used between the washers and the wheel.

The grinding machine of itself should be substantial and rigid, have well fitted

GRINDING WHEEL EQUIPMENT.

By Pedestal.

With a view to lessening the liability to accidents from breaking or bursting of grinding wheels, the Norton Co.,

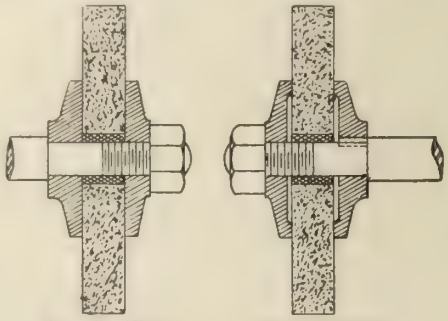


Fig. 1.—Wrong. Fig. 2.—Right.

Worcester, Mass., have applied themselves with much diligence and study to the question of equipment.

Results of experiments by them go to show that the wheels should be mounted on ample size spindles and that washers whose diameter is at least half that of the wheel be used as supports.

bearings and be securely fixed to proper foundations. Care should be taken to have the wheels true and in balance, and that the spindle hole admits of the wheel being slid on to the spindle without any appearance of play. The washers should be tightened just sufficiently to grip the wheel firmly without undue pressure.

To prevent work getting caught between the wheel and the rest, the latter should be adjusted as close up to the wheel as possible.

The speed of the wheels may be from 4,000 to 6,000 ft. per minute as required. All machines should be fitted with a sign or indicator denoting their wheel diameter and spindle revolutions. Worn down wheels may in this way be utilized on machines speeded to suit their reduced diameter.

Single pulleys are to be preferred on the machines, obviating as they do the starting of new wheels at excessive speeds.

Protective hoods with trunks to fan suction should be fitted to conserve operators' health, and the care of the equipment should be delegated to a responsible person. Fig. 1 represents an improper method of wheel attachment, while Fig. 2 shows that recommended.

CLEANING SHOP MOTORS.

By M. E. D.

The common custom in cleaning shop mators is to attach the air hose and blow the dust off the motor into the air where the men are working. In a wood-working department this is particularly offensive and is attended with a great waste of air.

A method adopted by the Toronto Steeet Railway Co., in cleaning the

cars is to use a vacuum system. The use of the vacuum system for industrial uses has been greatly extended in the past few years and there appears no reasonable reason why this system should not be applied to the cleaning of motors. The dust will be sucked out instead of blown out and the crevices in the motor will therefore be thoroughly cleaned out and the dust, instead of being blown into the atmosphere to be breathed by the workmen, can be collected into a receiver.

ROPE GROOVE GRINDING APPARATUS.

By Kelpie.

Inaccuracy of turning all the grooves on a rope pulley to the same gauge in the machine shop, and the subsequent installation of the pulley in the mill or factory, inevitably leads to operating trouble in the matter of unequal rope tension.

The apparatus here described and illustrated, Figs. 1 and 2, was specially designed to rectify such a defect at a lesser cost than that of dismantling the pulley and shipping it back to the machine shop. The sketches show it to be simple in constructional detail, of application to pulley widths between wide limits and adaptable to almost any local conditions. It is a useful portable tool for a jobbing machine shop to carry, occupying small space and of moderate weight for transportation.

The rope pulley requiring grinding had 23-1 inch rope grooves on a diameter of 40 inches. Its speed was 475 revolutions per minute.

The detail of the grinding equipment consisted of a shaft $3\frac{1}{2}$ inches diameter for a body length of about 6 feet and threaded $3\frac{1}{4}$ threads per inch. The ends of the shaft were turned down to $2\frac{5}{8}$ inches diameter to fit standard flat boxes. The lengths of these reduced ends were 13 and 27 inches respectively.

In addition to the large diameter being threaded, a keyway for fixing the grinding wheel was cut along its entire length. The emery grinder was 20 inches diameter and with its shaft had an operating speed of one half that of the rope pulley or 237.5 revolutions per minute. Adjustment was made by means of the keyway and locknuts as shown.

Further and closer adjustment of the grinding wheel to the side of the groove was got by the bridge screws on each end of the grinder shaft.

The emery wheel as will be noted has its grinding surface on one side only, by reason of which one side of each rope groove is completed in one lengthways operation. For the return, the emery wheel is reversed and the like process gone through until all the grooves have been treated. From time to time it was necessary, of course, to roughen and keep the emery grinding face true.

One difficulty experienced in tackling a job of this description, that is when the rope pulley has been in service, is the almost constant glazing of the grinder face by oil and grease secreted in small crevices of the various grooves, no matter how great pains are taken to have as far as possible complete extraction made before starting operations.

The drive, as will be noted from Fig. 2, is self-cootained. A single sheaf pulley 10 inches diameter is mounted on the driving shaft and roped to a similar pulley 20 inches diameter on the grinder shaft by an endless 1 inch rope and idler pulleys with weight tightener.

The whole equipment is reliable, compact and easy of application to a variety of installation.

Needless to say excellent, accurate and effective work was performed by the apparatus, with the result that an equable rope tension was attained at a comparatively low cost and with the minimum of delay and inconvenience to the regular operation of the mill.

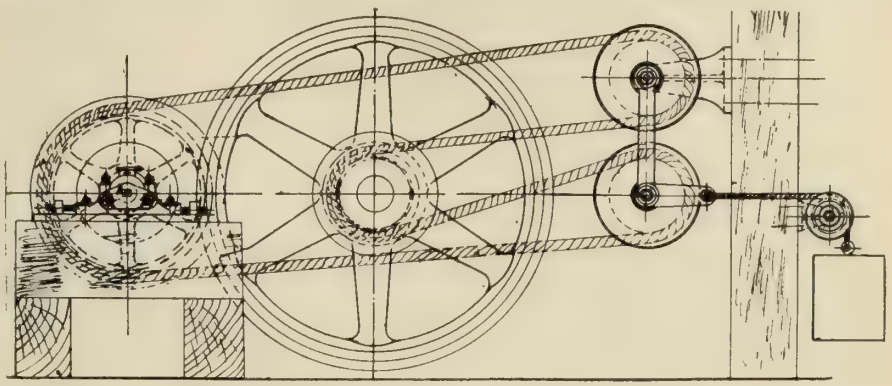

Fig. 2.—Elevation of Rope Groove Grinding Apparatus.

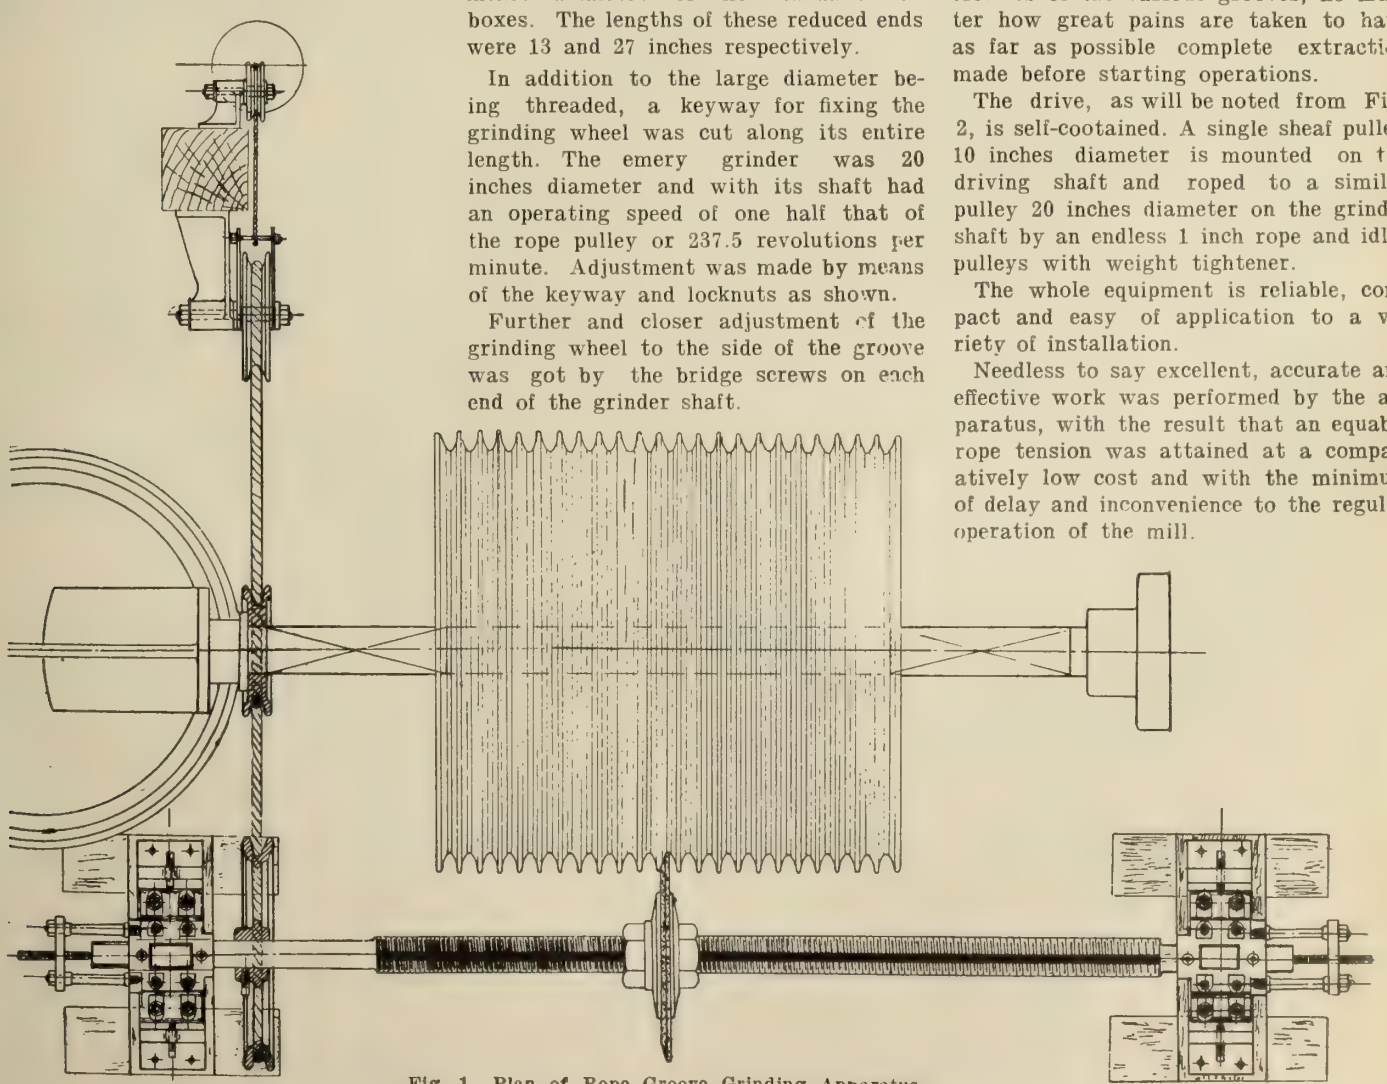

Fig. 1.—Plan of Rope Groove Grinding Apparatus.

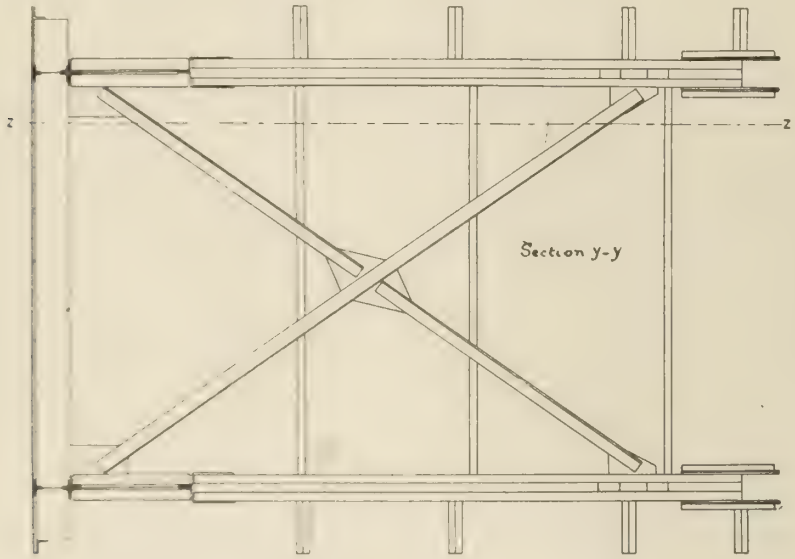
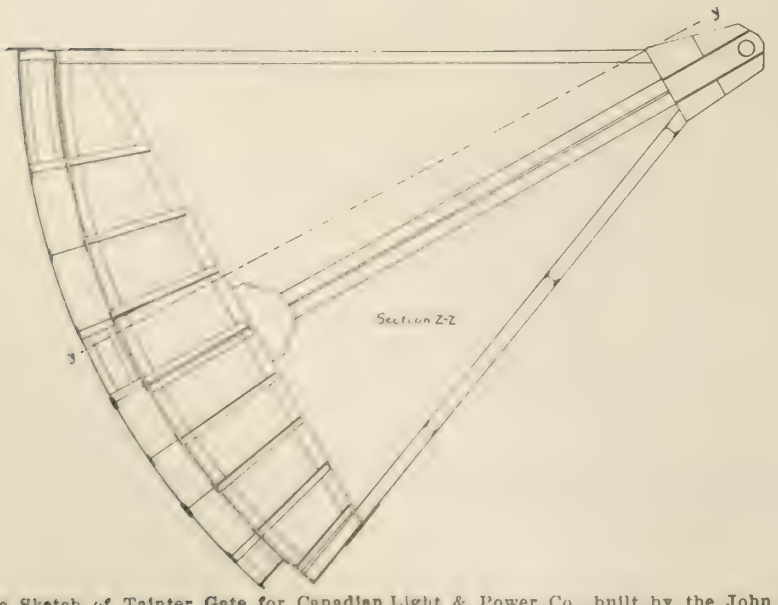


DAM OF UNIQUE DESIGN.



By M. E. D.

The John Inglis Co., Toronto, recently constructed a dam gate of unique design, for the Canadian Light & Power Co. It is known as the "Tainter Gate," and shows how the stresses increasing with the depth of water are taken care of in the dam. A side view is the shape of a segment of a circle as shown in the illustration.

The distances between the I-beams from the bottom up are approximately 1' 8", 2' 4", 2' 3½", 2' 5", 2' 9½", 2' 11", 3' 1" and 4' 6" which shows the relative pressure of the water at various points.

The upper half of the sketch shows a top view. The gates swing on the bearings shown. The plate into which the shaft fits is embedded securely into the concrete damp so that the Tainter gate is easily raised or lowered. Four of these devices were built, all the parts being carefully fitted before shipping.

Outline Sketch of Tainter Gate for Canadian Light & Power Co., built by the John Inglis Co., Toronto.

SIMPLE GRINDING FIXTURE.

By Donald A. Hampton.

I had been in charge of the shop but a short time when I was confronted with the job of reducing ten thousand pieces, like Fig. 3, to a uniform thick-

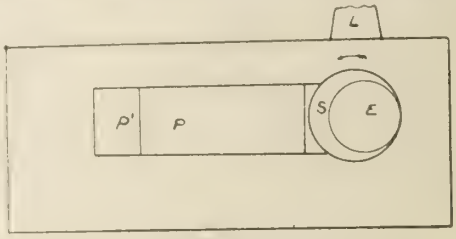


Fig. 1.

ness of 3-16 in. These had been cut from bars 1 inch in width and, while I would have preferred to "strip" them in longer lengths, the job was there and waiting and up to me. The steel varied a 1-64 inch, my given allowance was .001 in. above and .002 in. below actual size.

In the grinding room was a Norton grinder of the radial arm type which was unusually well supplied with gauges, angle plates, etc., and it was by use of one of these angle plates that I put the job through. Fig. 2. shows the device in perspective, the details of which are seen to a larger scale in Fig. 1. The angle plate was drilled for a shaft S which, at the back of the plate, was furnished with a lever L. The front end of the shaft was turned eccentrically as at E, for a distance equal to the thickness of the work pieces—3-16 in.—and hardened. A hardened piece P was made and inlaid

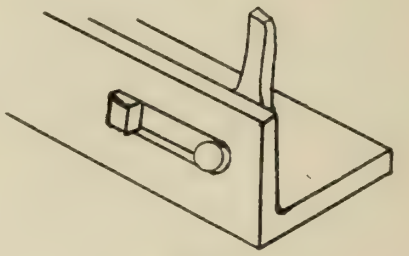

Fig. 2.

close up to the shaft S with the portion P extending beyond the face of the plate 1-16 in., as did also the eccentric end E. The fixture was then ready for work.

Now, with the lever adjusted in the right position, the work pieces were held most securely, at the same time quickly and easily, for ⅛ of a turn was sufficient to give the operator all the room needed for inserting. When the lever was released, the pieces fell off in a box. To offset the convexity of the stock, the part P was relieved through

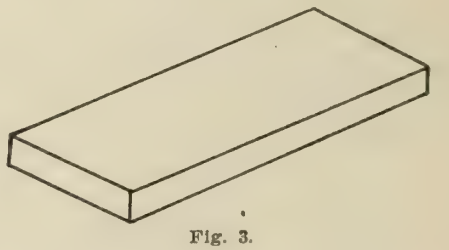

Fig. 3.

the centre and a clearance was provided next the shoulder P' for burrs and dirt.

To faciliate the work, a boy sorted the stock into three piles .005, 010 and .015 inches large, using an adjustable gauge for the purpose. The grinder first reduced the .015 inch stock to .010 inch, which was combined with the pile already waiting and this in turn further reduced. By so doing the operator's work was made uniform throughout, all pieces were passed across the face of the wheel the same number of times (3 or 4), and there were no excuses for slovenly work because of high and low stock creeping in.

PORT DRILLING JIG FOR PNEUMATIC HAMMER.

By Penstock.

The device here described is that used by the Maximilian Pneumatic Tool Co., Woodstock, Ont., for drilling the port holes in the cylinders of air hammers manufactured by them.

Fig. 1 is a sectional elevation of the hammer cylinder, the air ports in which, are indicated by the letters AA. These ports are each 3-16 of an inch in diameter and vary in number according to the power requirement of the hammer.

It should be noted that they are about 5 inches long and that the wall of metal on the inner edge after drilling is only

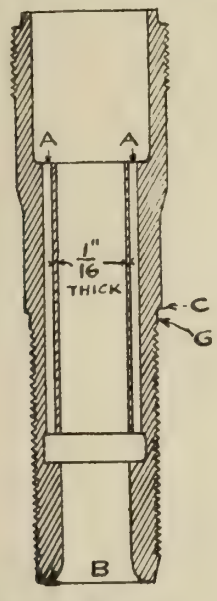

Fig. 1.—Sectional Elevation of Pneumatic Hammer.

1-16 of an inch thick. To secure accuracy of drilling, a suitable jig becomes therefore a necessity, and fig. 2 gives a representation of same.

The jig as will be seen has a large diameter machined base to which the body is bored and threaded square and true. The extreme diameter of the body is 3 inches, while that of the base is 8 inches. The thread, 8 per inch tapers from $2\frac{3}{4}$ inches to 3 inches diameter, ensuring with the 4 slots K, a compression grip when the nut F is screwed down. These slots are 3-32 of an inch wide by 5 inches deep.

Application consists in placing end B of the hammer cylinder into the jig barrel so as to bring its shoulder C to rest on the jig face D.

Tightening the nut F on the taper thread, locks the cylinder securely at its plain part G.

The nut F has a milled edge, and hand tightening of it is sufficient in all cases.

PORTABLE ELECTRIC OR AIR DRILLS.

By D. C. Current.

One of the handiest tools around a machine shop is the portable electric or air drill. Recently we experienced some trouble in erecting some agricultural machinery. Either the machine hands were careless or the jigs were inaccurate. In any case the bolts would not go where they were supposed to fit and it used up a lot of time and patience reaming out the holes by hand. The air was not piped to the warehouse so we purchased a portable electrical drill which has paid for itself many times over.

Later one hole was omitted altogether from several hundred frames. To send them back from the warehouse to shop would have caused a long delay and considerable expense. The portable drill

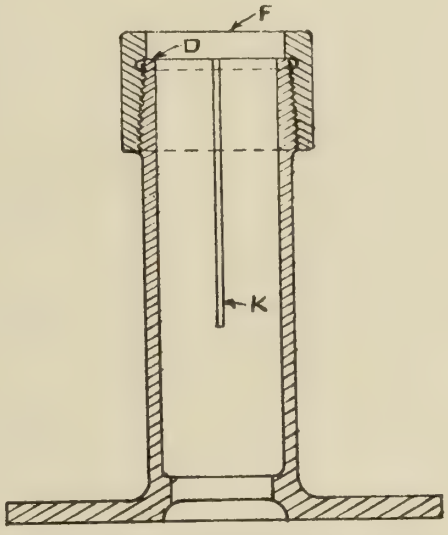

Fig. 2.—Sectional Elevation of Port Drilling Jig.

solved the difficulty and the machines were shipped on time. The portable drill whether air or electric is one of the best cost saving devices around the shop.

Correspondence

Comments on articles appearing in Canadian Machinery will be cheerfully welcomed, and letters containing useful ideas will be paid for.

Information regarding manufacturers of various lines, with their addresses will be supplied either through these columns or by letter, on request. Address letters to Canadian Machinery, 143-149 University Ave., Toronto.—Editor.

Use of Common Salt.

1. Please suggest the proper method of melting common salt in a crucible for heating tool or cast steel to the proper heat before being dipped into the cooling bath, for hardening.

2. Do you know of any substance to add to the salt to help it to melt at a lower temperature than when alone?

3. About what is the temperature at which salt will become a fluid?

4. Would you advise rock or common salt for melting in a crucible ?—A subscriber.

Replying to your favor, I must say that I have never heard of common salt (chloride of sodium) being used as a heating solution in tempering operations; a solution in combination with other chemicals such as alum, oil of vitrol or corrosive sublimate, may be used successfully as a cooling medium in tempering low carbon or inferior steels. —Reader.

Common salt which has a specific gravity of 2.16 has a melting point of 776 degrees. Plain sea water is used where any unusual degree of hardness is required and no temper is to be drawn, or on special steels such as soft centre plow steel. When sea water is not obtainable the following is a good substitute: Carbonate of soda, 2 lbs.; saltpeter, 2 lbs.; and salt 20 lbs. Dissolve in a barrel of water.

For hardening tools dissolve rock salt in rain water and use solution over and over again. The longer it is in use the better the solution for tempering.

Alloys of lead and tin, lead only and boiled linseed oil are also used for tempering.—M.E.D.

We would be glad to have any of our readers write us answers to the questions asked by this subscriber?—Editor.

FASTENING WORK ON PLANER.

By Machinist.

In the December 1910 and January 1911 issues of Canadian Machinery methods were given for holding work on a planer. I have a large number of flat castings to plane and experienced great difficulty in getting them true until the patternmaker came along one day and said he would soon remedy my troubles.

He put lugs on the side of the pattern with holes cored in them, making the distance between the centres of the holes equal to the distance between the centre of the T-slots in the planer. It is now an easy matter to bolt on the work for surface planing.

What are some of the uses to which aluminum is put? Is it an expensive metal?—A. B. Barron.

Aluminum is used to produce solid ingots and castings, for household utensils and electric transmission lines. If you write the British Aluminum Co., 24 Adelaide street, West, Toronto, they will send circular matter and lists. —Editor.

Vol. VII. April, 1911 No. 4

THE EFFICIENCY ENGINEER.

In our February issue, "Incompetency and Inefficiency" formed the subject of a brief editorial. We there stated that no data was available of basis or viewpoint of the estimator in the conclusions drawn.

Pushing our investigation a step further, we are at a loss even to locate the personality of the estimator. There is no trace of his origin, training, education, superlative intelligence and infallible reasoning; in fact nobody has ever met him, yet he seems existent.

Disciplinarians we know, inventors we know, experts in carrying out or doing special work we also know, and the big bluff we are certain of having seen and heard, but these men, these estimators, these efficiency engineers, who direct and operate through graded subordinates, everything under their care by increased competency to a higher plane of efficiency, we are strangers to unfortunately so far.

"Out of the fulness of the heart doth the mouth speak," and out of the emptiness of the head doth it at least likewise. Being so, the "big noise" may not necessarily count.

It strikes us that there is a too vague generalizing liberty taken by incompetents, and splarging of crazy ideals by idle dreamers.

"To make a silk purse out of a sow's ear" although yet impossible of attainment, has about as much probability of accomplishment as these hot-air effusions have of doing or being of any service to one branch or another of business or manufacture.

The incompetency and inefficiency cry is a fascinating one, and many are attracted to join in it, on account of the opportunity it affords of appearing famous in the public eye, at a cheap rate on a light-weight brain capacity.

The efficiency engineer as represented, is a myth so far as effective work performed is concerned. The name is being made a travesty of, by those who would cover up their own uselessness in displaying the weaknesses of others.

There is too much of the 5 cent moving picture show, prominent in the engineering profession and technical journalism to-day; too much dictation of what a man should be, and too little attention paid to means of realizing it.

Reckless and fiercely colored word pictures of what is expected and how far he falls short, unsettle him in his work and without doubt make him feel, "if I had the wings of a little dove, far, far away I would fly."

Cut out these ideas that a set of superior beings, know-it-alls, efficiency engineers or whatever you elect to call them, exist, and keep us from getting excited any more because we have never met them and are unaware of their name and address.

Let us get alongside the man at the machine, shovel or desk, give and get from him all the information and assistance he or we need or have at disposal.

Encourage a reciprocity agreement on similar lines between each man and the fellow at his shoulder; make them feel that the edging of one another further along the road of progress, accomplishes more than either could do for himself alone; and impress them that if they never meet the ideal efficiency engineer, they will have the personal satisfaction of laying claim to being at least, brands of the real thing.

ACCIDENTS, PREVENTION AND FIRST AID.

In this issue of Canadian Machinery is an article on "Safeguarding Machinery in Industrial Plants." Probably there is not a shop official including foreman, superintendent, master mechanic or manager who cannot recall an accident which happened in the shop under his charge and decreased the efficiency of his shop, and which the exercise of a little precaution in selecting machinery, transmission appliances, the wise expenditure on proper guards for gears, punches, etc., might have prevented.

Warning notices may be used to good advantage, but should be short and pointed. They give a protection from damage suits, but are not very efficient in preventing accidents.

In the best of organizations, accidents will happen and shop officials will find it to advantage to organize "first aid" corps who can give immediate and competent first-aid services within the plant to every injured person. The prompt cleaning and dressing of slight accidental wounds gives great relief to the sufferer and renders any later medical attention more effective. In the majority of cases nothing more is needed, but neglected or delayed treatment of simple injuries may have most serious consequences.

Every works executive and engineer will find it a valuable adjunct to the safety engineering of the plant to maintain in every department, apart from labor law and casualty insurance reports, a full and accurate record of every accident and also of every near accident. Periodical examination of these and the determination of every mechanical engineer to practice safety engineering to the best of his ability, without regard to the legal minimum or compulsion, will help more than anything else to remove speedily a great reproach from our industrial life.

THE STORES' DEPARTMENT.

It has been demonstrated that the plant that does not take proper care of its stock, is losing money and reducing profits. The system of piling stock in any out of the way corner of the plant yard exposed to the elements is rapidly becoming obsolete due to the foresight of those in charge studying the question intelligently. There are still some managers who have not yet heard of "Scientific Management" as far as the stock room is concerned. The writer visited one plant recently where two men were busy with shovels and axes trying to extricate some grey iron castings from the snow and ice which is so common in this country. In the not too careful endeavor to release them, several were broken and this loss was added to the wages of the men. It should not therefore, require much headwork to figure out the saving in providing a shelter for the output of the foundry before it is required for use in the machine shop.

In that plant there was no central stock room and when a workman erecting machinery desired some bolts he was allowed to help himself. If he had 100 pieces to put together and required 100 bolts, he generally helped himself to 110 or 115 in case there were some defective ones. When they were bolted in place, he found he had 12 or 15 bolts over. These were put under the bench for use some time hence and forgotten. When the next hundred was ready for erection there were another 115 bolts taken from the box and those left over were put away as usual finally finding their way into the sweepings that were thrown out.

Another incident that occurred was in connection with the blacksmith shop. When the foreman wanted stock he hunted it up and helped himself. One day he wanted stock for a certain job and in hunting for it, he came across some two inches too long. He had it wheeled into the shop, cut off the shears and forged into shape. Later he had another part for the same machine which required stock two inches longer than the first job, but on a hunt, all he could find was stock two inches too short. He had used the wrong stock. A consultation with the company's buyer would have put him right. A central stock room in charge of a competent man, would have eliminated all these wastes. It will pay you to have a proper stock department.

THE BUSINESS MAN'S AWAKENING.

Increased profits and more pay for the men by the application of Scientific management. Nearly every magazine, city daily and country weekly in Canada and the United States has had something to say about it, whether they knew anything about it or not. The fact is that the time to wake up has come for the shop manager, superintendent and foreman. "Rule of Thumb" methods have served in the drafting office and in the shop for years, but the days of such methods are passing for the wide awake shops. The change is not going to come about on account of some of the sweeping charges some papers make, but on account of the clear understandable concise way in which the technical press is placing before these men the results of experiments and studies along this line.

Charges have been made chiefly against the railroads. In a recent issue of the Atlantic Monthly, E. P. Ripley, president of the Atchison, Topeka and Santa Fe Ry. discusses the question and says :

> Railway managers do not deny that many mistakes have been made and many abuses have grown up in the development and administration of American railways. But they do deny the truth and fairness of many of the counts in the sweeping indictments of the roads that have been made and printed throughout the country, and feel strongly that most of the public hostility to the carriers is unjust. They do not doubt that the public means to be fair. But they feel that it has allowed itself to be misled, to its own injury, by those wholesale charges of wrong-doing. They believe that some of the legislation that has been passed recently is wholesome. But they think that many laws that have been enacted, and many projects for further regulation which are receiving popular support, are unwise, because they aim to do things that are undesirable, or to secure ends the attainment of which would be impracticable even if it were desirable.

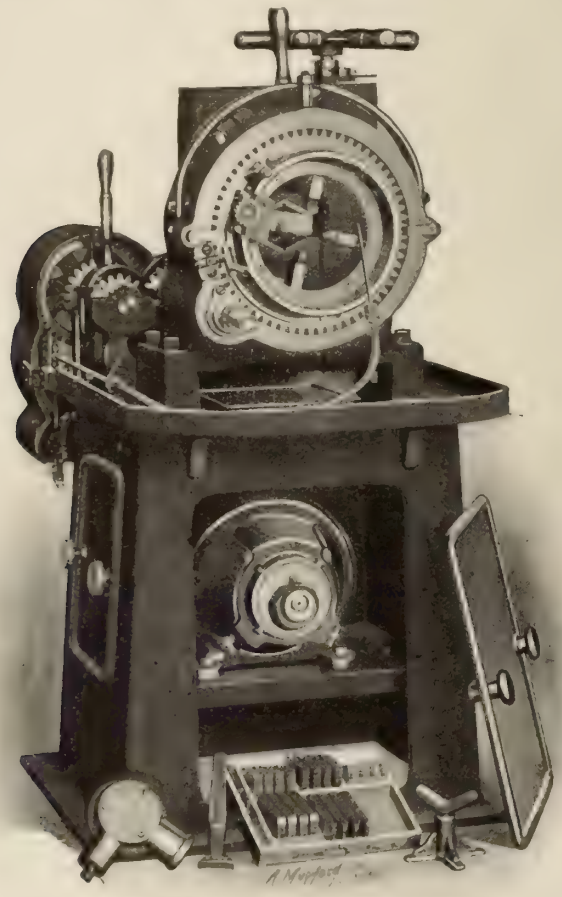
The fact is that such railroads as the Santa Fe, New York Central, C.P.R. and G.T.R., have been very progressive, as the systems of education, taking care of stock, tools, dispatching work, etc., have been kept up-to-date and men have been employed who are conversant with modern systems of business management.

A great deal may be gained by shop managers by watching someone else. "Many of our ideas," says Frederick W. Taylor, "we appropriated from some one else." But Taylor experimented too and one experiment alone saved $75,000 a year for the Bethlehem steel works. Taylor's experiments in the cutting of steel are now well known by every user of high speed steel.

The new movement is a world wide one and France and Germany are now trying it out. Each job must be studied separately, the handling of coal, sand, etc., drilling castings or performing any other work. There is one way which is quicker than any other way and the planning of the works will be rewarded by increased profits for the investors and increased wages to their men.

COMPENSATION FOR INJURED AND AGED WORKMEN.

In this issue of Canadian Machinery is an article on protecting machinery and thus minimize the possibility of accident. Accidents do happen, however, and employers should guard against them as much as possible. When they do occur it is only reasonable that some steps should be taken to look after the men's welfare.



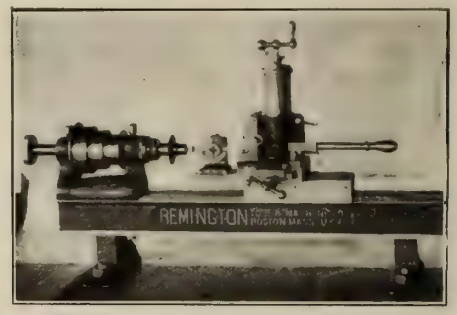
The same applies when a man grows old in the service of an employer. The Canadian Railroads recognize this and pension a workman after a certain number of years in their employ. If a firm or company buys a machine and pays for it he can do with it what he will but if he rents that machine and it is damaged, he feels in duty bound to replace it. When an employer rents a man's brain and hands, therefore, and that man is injured or grows old in his service, he should feel morally bound to recompense. The Canadian Manufacturers' Association have taken up the question and it is hoped something definite will result. The question is one that could be dealt with by the Provincial Governments and the Labor Department of the Federal Governments.

There is no better course of study for any apprentice or other young mechanic than to become as familiar as possible with the many names and terms used in the shops. While these vary in different sections, there are always enough floating from city to city from whom to learn many of the local terms with little trouble. While it would be difficult to put a pay-day price on this knowledge, no one can fail to be of more value who can call a tool or part of a machine by its right name, rather than to designate it as a "thing," preceded by one or more lurid adjectives.—Ex.

DEVELOPMENTS IN MACHINERY

A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, and Blacksmith Shop or Planing Mill.

MOTOR-DRIVEN PIPE MACHINE. The Curtis & Curtis Co., of Bridgeport, Conn., have just placed on the market, a new design of electrically driven pipe cutting and threading machines, as shown in accompanying illustration. The die cutting head is of the usual Forbes pattern, and is mounted on a cabinet base with a motor for any current desired concealed within.



New Curtis & Curtis Motor-Driven Pipe Threading Machine.

The machine is entirely self-contained, both as to the machine itself, and the way the power is applied. The entire machine can be moved from place to place, and started by simply attaching the wires. A trolley may be used over the machine to handle the pipe. The machine can be taken out on large jobs, and easily moved from place to place. Various speeds can be obtained, or the machine can be started or stopped by simply throwing a lever, while the motor is allowed to run constantly.

The motor being situated inside of the base, it is protected from drippings of oil, or breakage resulting from the handling of long and heavy lengths of pipe and fittings. The machine is very heavily geared with a very powerful motor, which provides ample power for dull dies or hard pipe. An economical feature is that the dies are clamped by one movement of a lever. The Curtis & Curtis Co. would be pleased to send special information in regard to these machines on application.

AUTOMATIC VARIABLE FEED. The accompanying half-tone shows the automatic variable feed to the head as applied to the Rockford shapers. It will be noted from the illustration that the arrangement has been designed with the view of simplicity and absence of complicated parts, making it serviceable and not liable to get out of order. It feeds the tool either up or down and operates at any angle. The triangular shaped incline on which the roller rides can be readily adjusted to suit the position of ram or moved out of the way when not in use.

The lever shown on the side of ram with spring pin, regulates the amount of feed. Six changes are provided, as follows: .008, .016, .024, .032, .040, .048. The lever on top of the ram reverses the feed and throws the gears out of mesh, by placing lever in central position when not in use.

Remington Bench Lathe.

The Rockford shaper is manufactured by the Rockford Machine Tool Co., Rockford, Ill., U.S.A.

UNIVERSAL HORIZONTAL BORING MACHINE. The accompanying illustrations show a new No. 3 size of the universal horizontal boring machine, recently placed on the market by the Universal Boring Machine Co., Hudson, Mass. This No. 3 machine, they term their 3" x 30" x 30", which refers to the size and travel of the boring bar; the machine has a 3 inch bar, a vertical feed of 30 inches and a horizontal travel of 30 inches.

Fig. 1 shows the spindle drive. The machine is of the single pulley type and may be driven from the line shaft. A shifter handle is located at B. The drive to the spindle is transmitted from the speed gear box through the vertical shaft E to the head proper. The exterior and interior details of the head are shown in Figs. 2 and 3. The head casting is one single casting, with oil pockets cored out in the casting itself for holding lubricant for the bearings and gears.

In Fig. 2 are shown the various operating handles, the handle A reverses the direction of rotation of the spindle by operating the jaw clutch J, as shown in Fig. 3. The handle B, operates the clutch O, Fig. 3, changing the machine from direct geared drive to back geared drive.

As will be seen in Fig. 3, the power is transmitted from the speed gear box through the shaft E to the spur gear F, then through G to the bevel gear H. The bevel gear H, I and I_2 together with the clutch J make up the reversing

mechanism. From the reversing mechanism the power is transmitted direct to the driving gear, when the clutch O is engaged with K; or around through the gears L and M, when the clutch is engaged with N.

The driving gear has been placed at a point nearest the work, as shown in Fig. 4, Q being the driving gear and P the driving pinion. This arrangement secures stiffness in large milling cutters, and at the same time eliminating chatter. The driving gear has a long hub, which forms the spindle and to the spindle are fastened two keys V and V_2, which drive the boring bar. The hub of the driving gear forms a face plate to which a face milling cutter may be fastened, four holes having been drilled and tapped out for the purpose.

The design of the head casting permits the rack S to travel the full length of the head, thus the hand wheel for the quick movement of the boring bar is able to be placed on the head well in towards the face of the spindle allowing the operator to see his boring cutters and make adjustments at the same time. A travel of 30 inches at one setting of the adjustable collar T is obtained. The automatic bar feed is received from the feed gear box through shaft B, which carries a worm meshing with the worm gear U. On the same shaft with this worm gear is the spur pinion which drives the rack. Referring to Fig. 2, E, is a positive clutch, which secures hand wheel D, to the worm gear.

The spindle proper is surrounded by an oil reservoir, the gears run in a bath of oil lubricated by the splash system and the oil reservoirs will be seen as indicated by the letters I, J, L, K, M, and N. This system of oiling consists of a wicking laid in a slot milled out of the bearing, the ends of the wicking dipping down into the reservoir below. The large reservoir for the lubrication of the main spindle bearings is filled at N, and drained at O.

The method of transmitting the automatic feed to the table is shown in Fig. 5. The table has been removed from the saddle, so as to show the details of the feed. The power is transmitted from the feed gear box through the shaft X which carries mounted on it a 45 degree spiral gear meshing with the 45 degree spiral gear W and a jaw clutch. The spiral gear runs free on shaft X, while the jaw clutch is keyed with a sliding spline. The spiral gear W carries the nut for operating the table feed and when the lever at the right of the saddle is pulled out as shown the jaw clutch engages corresponding teeth in the hub of the spiral gear beneath the saddle, thus engaging the feed. The stop Z is for throwing out the cross feed automatically. At Y is shown a nut secured to

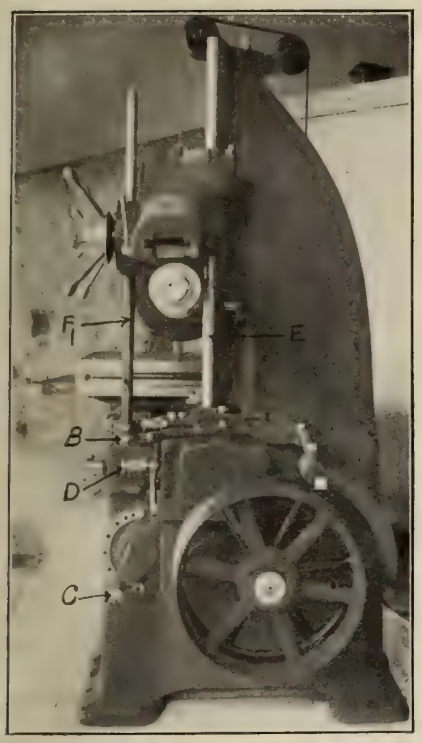


Fig. 1.—Spindle Drive Universal Horizontal Boring Machine Co., Chicago.

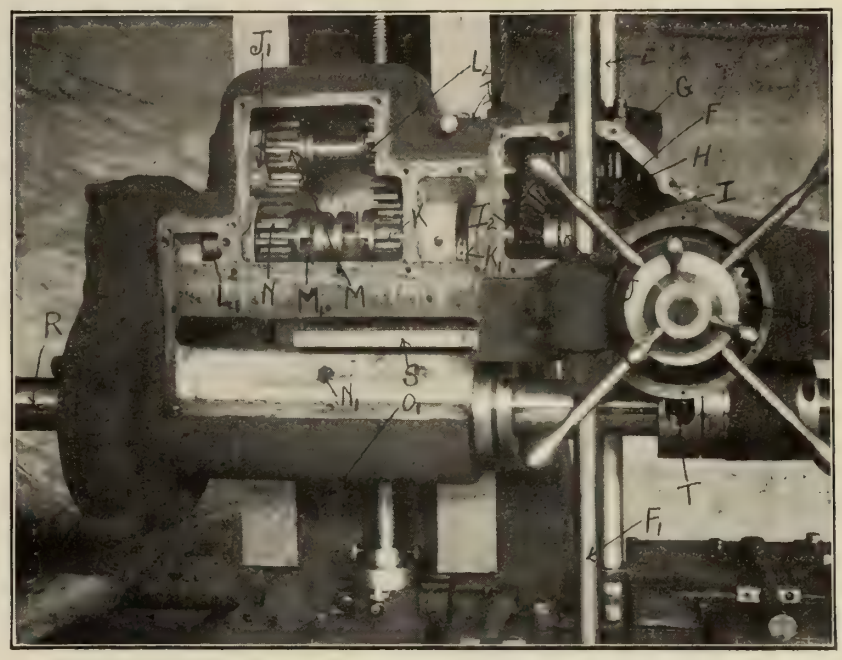

Fig. 3.—Power Transmission, Universal Horizontal Boring Machine.

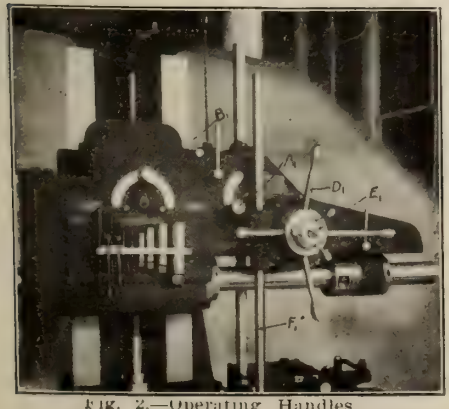

Fig. 2.—Operating Handles.

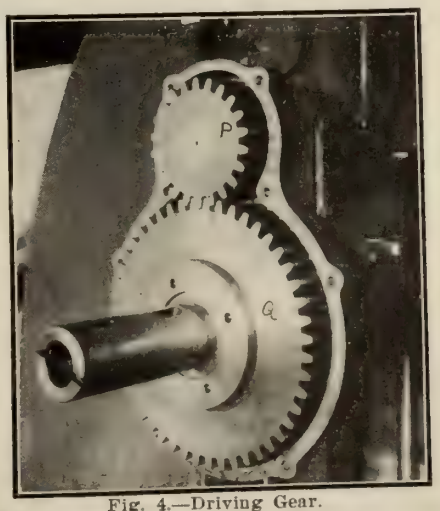

Fig. 4.—Driving Gear.

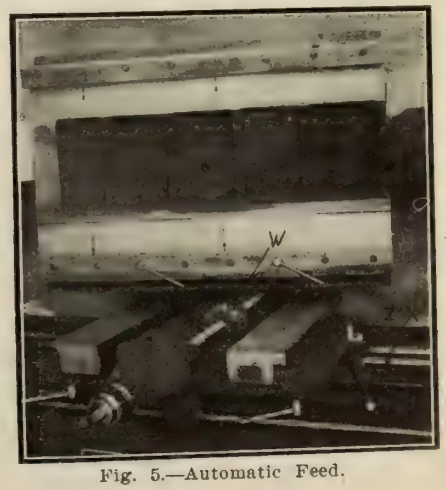

Fig. 5.—Automatic Feed.

the saddle so that the saddle and table have travel by power or hand longitudinally along the bed of the machine. Hand crank feed with micrometer adjustment is furnished for the operation of the table for longitudinal and cross movement as well as automatic feed.

The gear box contains the feed and speed change gears, which are made of steel; these gears run in a bath of oil providing sufficient lubrication, quiet running, and consequent long wear. Eight speed changes are secured from the gear box, by means of levers C and D, Fig. 1, and these are doubled at the head by the back gear lever, giving a range from 15 to 200 revolutions per minute. There are nine feed changes in either direction for the head, one lever reversing or stopping all feeds and retaining their relation to each other. The feeds range from ¾" to 5½" per minute without reference to the speed of the spindle.

INTERNAL GRINDERS.

The Bath Grinder Co., Fitchburg, Mass., have placed on the market attachments for their grinders for internal grinding. Fig. 1 shows the No. 5 machine with improved swivel head stock arranged to grind straight or taper work by the grinding spindle entering the hole from the back end, the headstock shown on the right with the water shield cover open, to true the wheel or mount or remove the work from the headstock.

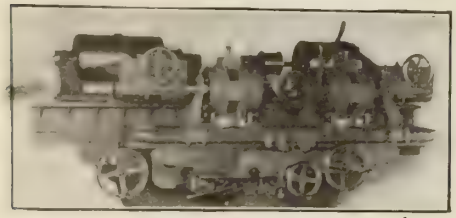

Fig. 1.—Bath Grinder with Improved Swivel Headstock.

Fig. 2 shows the same machine with special headstock furnished for grinding pneumatic hammers and long bushings.

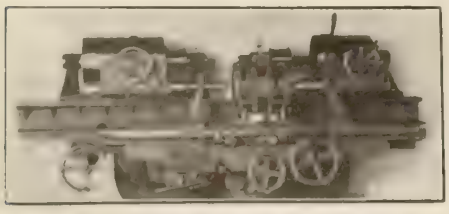

Fig. 2.—Special Headstock for Grinding Pneumatic Hammers.

Fig. 3 shows both No. 2½ duplex internal grinder. This machine has only one spindle head with two grinding spindles projecting from each side and driven by one belt. Fig. 4 shows this machine with the face plate and universal chuck mounted in the headstocks, with the grinding spindles entering from the back end. Fig. 5 shows the headstock reversed and the arrangement of grinding from the front end of the hole in place of the back end.

Fig. 6 shows improved swivel headstocks and assortment of work holding

Fig. 3.—Bath 2½ Duplex Internal Grinder.

fixtures furnished with No. 2½ and No. 5 machine. A gives an end view of the headstock furnished for grinding pneumatic hammers and long bushings. B shows 4½" steel spring collet. C shows a set of reducing bushings furnished with B spring collet for reducing the hole to size. These bushings are furnished in 8 sizes. D shows a step spring chuck, with jaws for holding work that cannot be held inside of the spring chuck. The

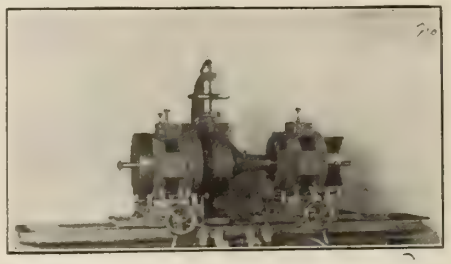

Fig. 4.—Face Plate and Universal Chuck Mounted in Headstock.

reducing bushings C can also be furnished with spring chuck D. E shows the 4-jaw independent chuck mounted on quill, and is held in the spindle head, the same as B or D. F shows face plate. H and I show spindle heads as shown with machine in Fig. 1 and 3.

Fig. 7 shows 8 sets of internal manufacturing spindles for No. 2½ and No. 5 grinders. A shows a set of large spindles made from one solid piece of steel. B shows a set of spindles that are used with No. 2½ and No. 5 machine, mounted

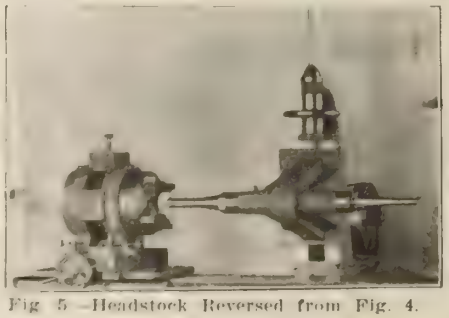

Fig. 5.—Headstock Reversed from Fig. 4.

in base plate, as shown in Fig. E. Sixteen diameters of spindles are made from stock of 3" diameter, and the ends reduced to the diameter of the hole to be ground. The grinding spindles have a

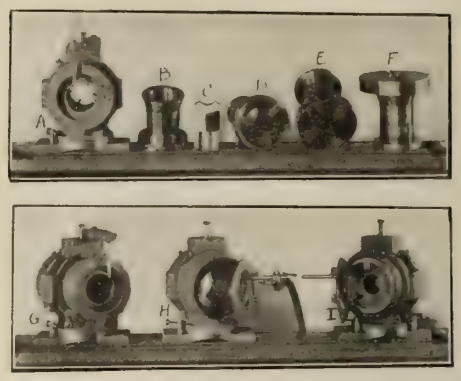

Fig. 6.—Swivel Head Stocks, Bath Grinder.

large body of metal at the back end, which absorbs the vibration of the high speed grinding spindle, and absorbs the heat generated at the small end of the spindle, and permits the grinding spindle to run at a higher speed. The bearings are made from Tobin Bronze, and the grinding spindles hardened, ground and lapped. There are no oil holes in the body of the spindles. They are oiled from the back end, which makes them dust proof, and the machine does not have to be moved out of position to oil them.

Fig. 8 shows application of 8 grinding wheels, and method of holding and grinding a divided gear on a gear-hobbing machine, internally from the back end and the front end at the same time, externally on the periphery and side.

ADVANCE IN MACHINE TOOLS.

The developing of machine tool construction and its advances in recent years, was the subject of a lecture given last night before the mechanical section of the Canadian Society of Civil Engineers by Colonel Alex. Bertram, of

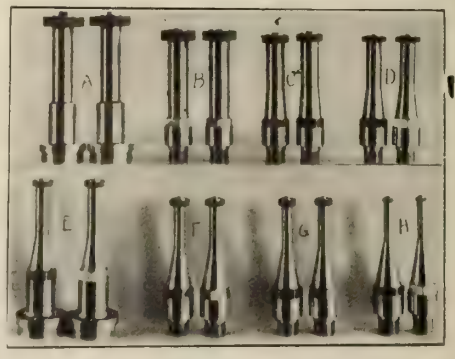

Fig. 7.— Internal Spindles.

John Bertram & Sons Co., Dundas. The chair was occupied by Mr. H. H. Vaughan, and there was a large attendance of members. The lecture, which was illustrated by lantern slides, demonstrated the advance made within the last half century and more particularly in the last decade in machine tool invention.

POWER EQUIPMENT & APPLICATION

Expert Descriptive Articles Dealing with Selection and Purchase of Most Suitable Power Equipment for All Purposes, its Proper Application, Installation, Operation and Treatment.

GEARS AND GEARING*

By A. E. B.

TOOTHED wheel gearing is used to a lesser or greater extent in a variety of circumstances for the transmission of motion and power from one shaft to another. It has the advantage of precision over belts and ropes in this respect.

In its design and arrangement, the idea aimed at, is to have the minimum of friction, an absence of noise, a constantly equal power transmitted and the principle of two plain cylinders rolling on each other by the friction of their surfaces, approached to as closely as possible.

The diameter of the pitch circle, or in other words what would be the diameter of a plain cylinder, is reckoned as the wheel diameter, and as a result when two wheels gear properly, their pitch circles meet and roll upon each other.

Pitch of Gears.

The most important measurement of a gear is known as the pitch and there are two distinct systems of determining it, namely, the circular pitch system and the diametral pitch system. The circular pitch is the distance between any point in a tooth and the corresponding point in the next tooth measured along the pitch line. The diametral pitch is the ratio of the number of teeth in a gear to the pitch diameter. For example, a gear of 12-inch pitch diameter having thirty-six teeth would be known as a three-pitch gear. The advantage of this system is to avoid uneven diameters, as would follow by making a thirty-six tooth gear of one inch circular pitch. The pitch diameter in such a case would be 11.46 inches.

$$\frac{36 \times 1}{3.1416} \text{ equal } 11.46.$$

Cast iron and mortise gears are measured on the circular pitch system and cut gears on the diametral pitch system.

Fine pitch wheels have a smoother and more uniform action than coarse ones, therefore the pitch of teeth should be designed to secure this operating condition as far as consistent with the power to be transmitted.

Methods of Manufacture.

Touching methods of manufacture, the following may be taken as those commonly adopted:

Cast gears, the teeth of which are formed by the pattern and cast to shape.

Cut gears, the teeth of which are cut from a solid casting by standard gear cutters.

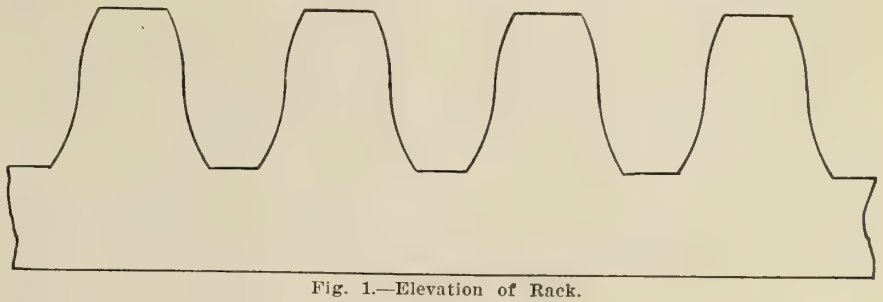

Fig. 1.—Elevation of Rack.

Mortise gears, the teeth of the larger of the pair having mortises in the rim into which are driven maple or beech teeth well seasoned, the teeth being keyed tight on the inside of the rim and accurately dressed to shape.

Types of Gears.

The principal types and forms of gearing in general use may be classified as follows:

Spur gears, the axis of whose shafts are parallel. Oblique tooth spur gears, whose teeth are at an angle with their shafts; known as double helical when the teeth are also angular in shape, and have their two ends on a line parallel with the shaft. They are known as single helical when the teeth are straight. This class of spur gear runs much more smoothly than the ordinary.

Internal spur gears, have the teeth on the interior of the rim and pointing in the direction of the shaft. This class of gear is the strongest for a given pitch, and is used largely to economize space. Internal spur gears rotate their shafts in the same direction.

Elliptical spur gears, have their shafts off the centre.

House tooth spur gears, have a portion of their teeth encased between flanges.

Bevel gears have the axis of their shafts on the same plane and at right angles.

Mitre gear is the term used when both are of the same size.

Angle gears have the axis of their shafts on the same plane and at an angle other than a right angle.

Worms and worm wheels have the axis of their shafts at an angle but not on the same plane. A movement of the wheel equal to the circular pitch results in a complete revolution of the worm.

Rack and pinion gears are used for the purpose of changing their relative position to each other by a parallel movement.

An intermittent gear derives its name from the intended purpose to stop the driven gear for any given period of time. It is accomplished by forming the driver without teeth at definite intervals desired.

Wheel and pinion are the names applied to the larger and smaller units constituting one pair of gears.

*Part I. of the third article of the series of Power Transmission Equipment, Operation and Efficiency Subjects.

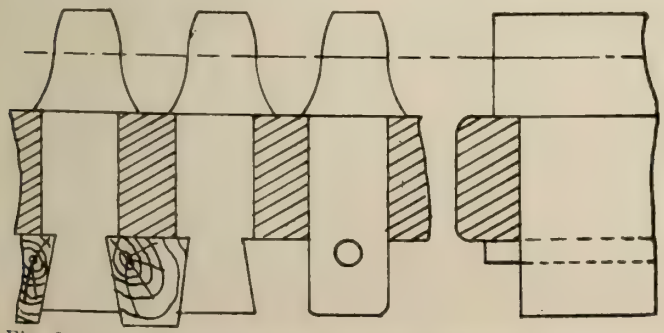

Fig. 2.—Mortise Teeth showing Wedge and Steel Pin Attachments

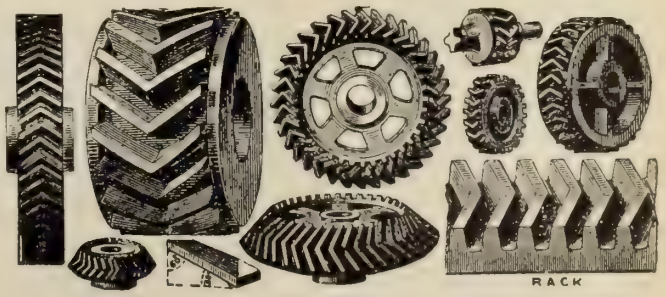

Fig. 3.—Miscellaneous Double Helical Tooth Gears.

Two gears are said to mesh when their teeth are engaged properly.

Miscellaneous Definitions.

The pitch line or circle is the path described by that point of intersection between the teeth where the speed of both gears is equal. The pitch line of bevel and angle gears is measured at the largest diameter.

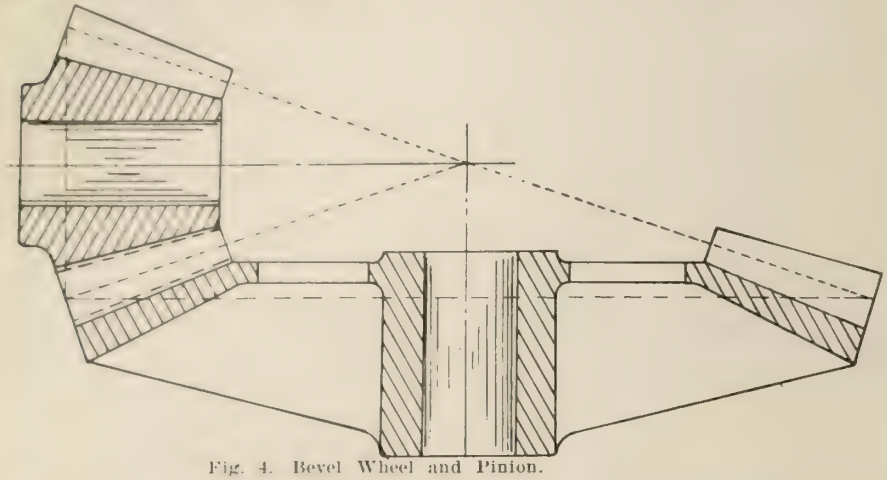

Fig. 4. Bevel Wheel and Pinion.

The addenum circle is the path described by the extreme outer end of the teeth.

The addendum is that portion of the teeth between the pitch line and the addendum circle.

The root circle is the path described by the extreme inner end of the teeth.

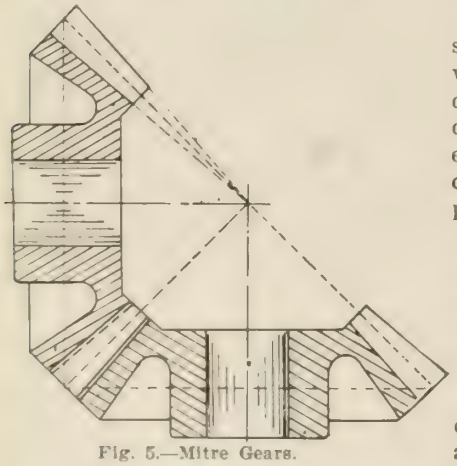

Fig. 5.—Mitre Gears.

The root is that portion of the teeth between the pitch line and the root circle.

The outside diameter is measured inside the addendum circle.

The root diameter is measured inside the root circle.

The pitch diameter is measured inside the pitch line.

The pitch radius is the distance between the centre of the gear and the pitch line.

The line of centres is the distance between the centres of a pair of gears in mesh.

The length of tooth is measured between the root circle and the addendum circle.

The breadth of tooth is measured across the face of the gear.

The thickness of tooth is measured along the pitch line.

The space is the distance between the teeth measured on the pitch line.

The backlash is the difference between the thickness of tooth and the space.

The end clearance is the distance between the addendum circle of one gear and the root circle of the other when in mesh.

The backing of bevel gears is the distance between the pitch circle and the extreme end of the hub.

Speed of Gears.

The speed at which gears may be safely run consistent with moderate wear and tear varies considerably in the opinion and practice of operators and designers. The following are however examples of what may be considered common and reliable performance in feet per minute:

Ordinary cast iron wheels, 1,800.
Helical cast iron wheels, 2,400.
Mortise wheels, 2,400.
Ordinary cast steel wheels, 2,600.
Helical cast steel wheels, 3,000.
Cast iron machine-cut wheels, 3,000.

Gears made of rawhide or fibre can be operated safely at a higher speed and are generally superior for wearing qualities, although not as strong as metal gears.

NEW STEEL PULLEY.

A new steel pulley is being placed on the Canadian market by Schuchardt & Schutte of Montreal, Que., which has several interesting features. The pulleys are all steel and are light and strong.

The rim is composed of two layers locked together. The ends overlay the arms and bolts which hold the two halves of the pulley together, pass through the hole, which prevents the danger of stripping rim and ensuring great strength to the arch forming each half pulley.

The construction of the arms combines great strength with light weight. In all pulleys eighteen inch and upwards the arms have openings to reduce weight. Pulleys thirty-six inch and upward have four arms. All sizes of pulleys have one uniform bore for taking bushings of one uniform outside diameter for different sizes of shaftings. Stamped steel bushings are supplied to adapt the pulleys to smaller diameters. These bushings have a very fast grip on the shaft and eliminate to a great extent the danger of turning loose. No rivets or bolts are used in the construction of the pulleys.

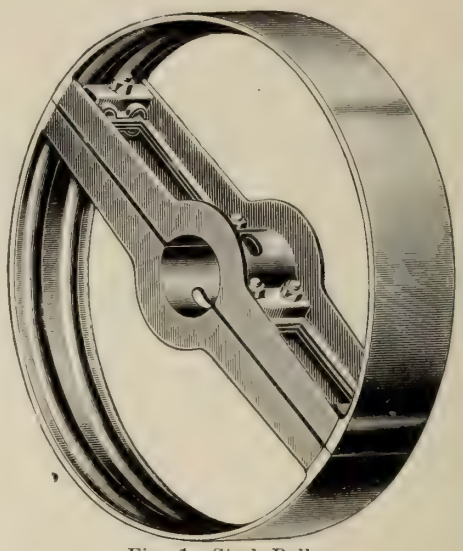

Fig. 1.—Steel Pulley.

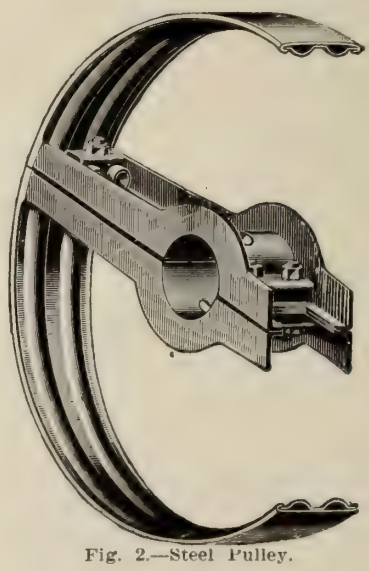

Fig. 2.—Steel Pulley.

The pulleys are manufactured in very large quantities with very heavy presses, a special die being used for each size. Their accuracy in running true is obtained by rolling all the steel plate, entering into the manufacture of these pulleys before it is used, with the aid of very heavy rolling mills, securing an accuracy of .00039 in.

SYSTEMATIC BUSINESS MANAGEMENT

Practical Articles for Managers, Superintendents, and Foremen, to Assist in Carrying on the Business Economically and Efficiently.

PRODUCE.

By Service.

The office is made to sell and the factory to produce. These are the two general divisions. If this be so, why not make the factory produce and produce efficiently without any peak loads. "How shall I do it?" is the natural question. Some managers and superintendents have tried some schemes and some others. Some have been successful, and some haven't. Some have tried schemes of rewarding men, some have installed systems, yet the factory failed to produce more than previously.

The trouble is that the business managers fail to use the knowledge they acquire in the management of their own plant. They know of obstacles and pitfalls into which others have fallen but do not try to avoid them. Men do not like being told so but it is true, nevertheless.

The writer had to learn by experience and only a fool will not listen to experience. It is easy to point to failures. It is easy to point out where men may fail but that is not the purpose of this letter. ITS OBJECT IS TO TELL MEN HOW TO FORESEE, AVOID AND OVERCOME OBSTACLES AND MAKE THE FACTORY PRODUCE.

How to Produce.

"NEVER PUT OFF 'TILL TO-MORROW WHAT YOU CAN DO TO-DAY." It is the easiest thing in the world to pigeon-hole seemingly unimportant things and say, "I'll attend to that to-morrow." Better do away with the roll-top desk if you use it for that purpose. It was never intended for that. Finish everything as it comes and you will be surprised what it will mean in the way of production.

2. STUDY MEN. You are in constant touch with the men. Your position as manager, superintendent or foreman calls for it. Sometimes a man comes into the office asking for a raise. You are busy at something else and dismiss him with a curt remark. You have offended him and his rate of production is lowered. If you are busy, say so. Tell him you'll talk about it to-morrow and if he isn't worth a raise give him something to hope for. One reason why Clarence S. Funk rose from a $10 a week clerk to the general managership of a $140,000,000 corporation was because he studied men. Mr. Funk says: "They must be treated as friends and co-workers." Give them some responsibility, make the men self-reliant yet obedient. Teach them to say yes or no. Encourage them. Be absolutely fair.

You can get the men to take a partner's interest. Large companies are beginning to realize it. Libraries, hospitals, educational classes, etc., are not furnished and financed for pleasure or philanthropy. It is a business proposition. Men appreciate it and it has a marked effect on the production. "First Aid" means that men are promptly attended to in the case of injury and very often no time is lost by them where otherwise they would be greatly weakened and be on the sick list for some days seriously affecting the organization and output.

PRODUCE!

One Dollar that is Earning Interest is More Valuable Than Two Dollars That are Earning None—

A Humble Talent that is put to Use is Worth More than Genius Lying Idle—

A SINGLE IDEA THAT IS CONVERTED INTO ACTION IS DOING BETTER SERVICE THAN A THOUSAND IDEAS THAT ARE UNEXPRESSED—

A Menial Job that Brings in Real Cash Pays More Bills Than the High-salaried Position in Prospect—

The Pennyworth that is Sold Spells Bigger Profits than the Dollarworth that Stays on the Shelf—

A Bird in the Hand is Worth Two in the Bush—

SAY IT WITH AS MANY FRILLS AS YOU WANT, THE POINT IS THIS:

DO SOMETHING. DELIVER THE GOODS. PRODUCE!

—System

INTERFACTORY TRANSPORTATION. Did you ever enter a shop and see five of six men moving a large casting from the foundry to the machine shop, or from the machine shop to the shipping room. A great deal of waste time and effort can be entirely eliminated by a good crane service or an industrial track connecting the departments. One man could then handle large castings and the time of the other four or five men could be used to good advantage to increase the output of the plant.

In shipping it is advantageous to have the top of the car level with the floor unless cranes may be used. The direct loading of small castings or boxes will be found to be more quickly than by a crane. Some plants have to transport the product of the factory to the station by waggons or motor trucks. The lowered portion will be found to be of equal service here when the trucks are the same level as the shipping floor.

Scientific Management.

The fact is that all the points that could be brought up, would fill volumes. The manager must do some "digging" in his own plants. There are efficient and inefficient ways of doing things. The methods should be investigated and corrected. Perhaps there is insufficient light, the tool room is not convenient, there is insufficient equipment, or cuttings that could used to manufacture something and produce a profit are thrown under a boiler. There are a thousand and one wastes that should be investigated and eliminated. The scientific manager will find them out, and plan the work.

A locomotive under one master mechanic may cost $100 to repair but be back in the repair shop in a month. A successor may repair it at $125 and it will stand hard service for three months. Evidently the second one has discovered the secret of wise expenditure. MAKE EVERY DOLLAR BUY ITS FULL EQUIPMENT IN STANDARD PREDETERMINED SERVICE AND IN THE FACTORY MAKE EVERY DOLLAR COUNT IN SECURING INCREASED EFFICIENCY.

In plaster of Paris molding, the usual difficulty is in not completely drying the mold. Unless it is "bone dry" the metal will not fill the mold as the steam produced from the dampness will blow the metal away from the surface of it. In order completely to expel all the moisture from the mold, it must be heated nearly red hot. It should also be used while warm, in order to prevent absorption of moisture from the air.

Metals should not be melted too rapidly or certain portions of them will become overheated before the rest arrive at the melting temperature. The best condition is when all of the metal arrives at the melting point at practically the same time. This is difficult to realize in practice, but should be attempted.

THE FACTORY TELEPHONE.

By Efficiency.

THE factory telephone which formerly was considered a luxury is now regarded as a necessity in every business as a time saver. The present shop organization includes automatic telephones for communication between all departments.

The very nature of the modern machine shop organization with its various departments covering a large ground area demand that some quick method of communication be installed that will put every department in close touch with any and every department and IT SHOULD NOT BE NECESSARY FOR THE FOREMAN OF, SAY, THE MILLING DEPARTMENT TO GO TO THE FOUNDRY TO ASCERTAIN WHY CERTAIN CASTINGS REQUIRED FOR A RUSH ORDER HAVE NOT REACHED HIM. HIS TIME IS TOO VALUABLE TO BE THUS WASTED. Again, the shipping department, located perhaps in a remote part of the works, should be in as close touch with the superintendent as the drafting-room just outside his office.

The value of the automatic telephone is shown in its low initial cost and cost of upkeep and in the saving of time, thus increasing the efficiency of high paid officials. Formerly when the superintendent wished to communicate with a departmental foreman, he had to hunt him up in his department and deliver a minor instruction that could as easily, have been delivered by telephone.

The reverse is also the case. Formerly when a foreman wished to find the superintendent, he traveled to the superintendent's office and nine times out of ten found him out, as the superintendent's duties took him all over the plant. Then he hunted for him in the stock room, foundry or some of the other departments, at last discovering him after the lapse of half an hour or more. During this time the department was without a foreman. Now with the telephone, the foreman need not leave his department. He presses a button on the telephone and at once gets into touch with the superintendent, whether he is in his own department or another.

By the factory telephone not only may the superintendent be located in a hurry, but also any others who may be making a tour through the works. In a few moments all the stations can be called up if necessary, the desired persons located, and any communication transmitted or information obtained with promptness.

A superintendent's call instrument may be used at any station in connection with the automatic factory telephone to enable a general call being given throughout the system for the superintendent who may be in one or another of the departments. For this purpose there is required a button in each set, or a separate push button, for each station from which it is desired to send in a general call for the superintendent; a call bell for each department outside of his own in which the superintendent is likely to be engaged; a battery and a pair of wires in the cable connecting the different stations, or a twisted pair of No. 19 B. & S. gage rubber covered copper wires.

Operation.

In the automatic factory telephone, connection between stations is established by simply pressing a button. One button is mounted on the set for each of the stations connected to the system. A name plate is provided with space opposite each button for designating the name or location of the station

The Automatic Office Telephone.

associated with the button. The same button is used both for signaling the station desired and for establishing the telephone connections. The operation is therefore very simple.

To make a call, press way down the button opposite the name of the station desired; this places the key in its ringing position. Then release the pressure on the button and the key will return to its talking position. Remove the receiver from the hook and place it to the ear.

To answer a call press the button designated "Ans."; remove the receiver from the hook and place it to the ear. After a conversation is finished it is not necessary to release the button as it is automatically restored when the next connection is established.

DUMMY WAITER AND SPEAKING TUBE SAVES MONEY.

By M. E. D.

The dummy waiter and the speaking tube are finding an increasing use in the factory. One plant with which the writer is familiar has a speaking tube between the store room and cost clerk's office. In another there is a speaking tube between the order and stock departments. Some time ago the National Cash Register installed a dummy waiter between the machine shop and the stores department on the floor below. The stock is sent up by the man in charge of that department without the necessity of another man or delays in delivery.

In the machine shop of the Smart-Turner Machine Co., Hamilton, a combination of this system has been installed by R. McKechnie, the superintendent. In order to provide larger space for shop equipment, the tool room and stock departments were removed to the galleries. When a workman required stock or a tool, he had to climb a stair to the gallery, requiring considerable time during which his machine was idle.

The difficulty was solved by installing in a convenient position, a dummy waiter and speaking tube. Now when a workman requires stock he sends up a properly signed requisition, or if he requires a certain tool he sends up his check and calls up the man in charge of the tool room. If any explanations are desired they may be made by means of the speaking tube. The tool-room and stock departments are adjacent and the one installation serves for both.

ALUMINUM BRONZE.

An article in the "Brass World" by E. S. Sperry states that aluminum alloys with copper in all proportions and homogeneous mixtures are produced. When the Al. reaches beyond 10 p.c. the bronze begins to become brittle, and a 12 p.c. mixture is so hard that it may be used for hard dies. The mixture generally used for sand casting is the 10 p.c. alloy It is hard and tough and answers all the requirements of a strong metal. The greatest difficulty in the way of casting Al.-bronze is its oxidation when melted. The only method by which it can be cast in a commercial manner is to prevent its being agitated while the pouring is taking place. The more quietly it can be poured the smaller the quantity of dross. Dross which forms in melting may be skimmed off, but that which forms while the pouring is taking place enters the casting. Another difficulty in casting the alloy is the shrinkage of the same; but by the use of sufficiently large risers and freedom from sharp corners in the casting with an ample gate, any shrinkage may be readily overcome. The toughness of Al. bronze is probably greater than that of any metal except steel. All bronze works hot better than Cu. as it is softer at a red heat. At the same time, it is not black-short like the Cu. and Zn. alloys.

FOUNDRY PRACTICE AND EQUIPMENT

Practical Articles for Canadian Foundrymen and Pattern Makers, and News of Foundrymen's and Allied Associations. Contributions Invited.

PITTSBURGH CONVENTION.

Owing to the big demand for exhibition space, the Foundry & Machine Exhibition Co., successor to the Foundry & Manufacturers' Supply Association, has been obliged to arrange for additional space in the Western Pennsylvania Exposition Society buildings, Duquesne Way, Pittsburg, for the exhibition of foundry and pattern shop equipment, machine tools and supplies, to be held in May.

It has also been decided to open the exhibit Tuesday, May 23, instead of May 22, as originally arranged, and to continue the exhibition over the first four days of the following week. These changes were decided upon at a meeting of the executive committee of the Foundry & Machine Exhibition Co., at the Fort Pitt hotel, Pittsburg, Saturday, March 4. Originally the committee arranged for a total of 28,000 square feet of exhibit space in the Western Pennsylvania Exposition Society buildings and 23,000 square feet of this space was sold within two weeks from the time bids were opened. At the meeting, March 4, the committee made arrangements for the whole of the main floor of the larger building, which will give a total of 40,000 square feet of exhibit space, which is about 8,000 square feet more than used in past years.

The decision to continue the exhibition into the second week has been made on account of the annual meeting of the American Society of Mechanical Engineers, which will be held in Pittsburg that week.

The annual conventions of the A.F.A., the A.B.F.A. and the American Foundry Foremen's Association, will be held during the first five days. The meetings and exhibits should attract large numbers of men interested in the manufacturing industries and it is hoped a large number of Canadians will avail themselves of this opportunity of seeing side by side the various types and makes of molding and pattern-making machinery and machine tools. The exhibit will be open from 8.30 to 5.30 daily and two or more evenings subject to the decision of the management.

Some men are so full of faith in themselves that there is no room left for ability.

The man who is always looking for precedents must keep his face turned to the rear.

PITTSBURG CONVENTION PROGRAMME.

American Foundrymen's Association.
American Brass Founders' Association.
Associated Foundry Foremen.
Foundry and Machine Exhibition Co.

PITTSBURG FOUNDRYMEN'S ASSOCIATION will properly entertain those attending the Conventions, and have made special arrangements for the visiting ladies.

PRELIMINARY PROGRAMME.

(All at EXPOSITION BUILDINGS, unless otherwise stated.)

MONDAY, May 22—2 p.m.—Registration only.

TUESDAY, May 23—9 a.m.—Registration.

10 a.m.—**Joint Session**—Addresses of Welcome—Papers on:—

Production Cost.
Economic Foundry Insurance.
Uniform Contracts, etc.

2 p.m.—**Separate Sessions.**

A. F. A.—Papers on:
Unloading Methods.
Use of Borings in Cupolas.
Effect of alloys in Cast Iron.
Permanent Moulds, etc.

A. B. F. A.—Papers on:
Vanadium in Non-ferrous Alloys.
Determination of Nickel in Bronzes.
Pouring High-grade Bronzes, etc.

7 p.m.—**F. & M. E. Co. — Exhibit** — Open throughout the week during the day, and Saturday evening, May 27th.

WEDNESDAY, May 24—9.30 a.m.—**Joint Session**—Papers on:
Rotary Blowers.
Foundry Construction.
Heating and Lighting Systems.
Pattern Making.
Molding Machines, etc.

2 p.m.—**A. B. A. Steel Session**—Papers on:
Acid and Basic Open Hearth Processes.
Electric and Converter Furnaces for Steel Castings.
Effect of Vanadium and Titanium on Steel.

2 p.m.—**A. B. F. A. Session**—Papers on:
Corrosion of Brass Foundry Products.
Pyrometer and the Aluminum Foundry.
Non-ferrous Foundry Economics.
Equilibrium Diagrams, etc.

2 p.m.—Individual Plant Visitation.

6.30 p.m.—**Dinner**—Pittsburg and Associated Foundry Foremen. (Will announce place later.)

THURSDAY, May 25—**Joint Session.**

9.30 a.m.—Papers on:
Molding Sand.
Use of Alloys.
Shot in Castings, etc.

1 p.m.—Train Excursion to Foundries and Steel Works (Pennsylvania—Union Station.)

8 p.m.—Entertainment by Foundry & Machine Exhibition Co. to Members of all Associations and their guests attending the Conventions.

FRIDAY, May 26—**Separate Session.**

9.30 a.m.—Election of Officers and reading of papers.

3.30 p.m.—Pittsburg and Cincinnati ball game at the Million-dollar Forbes Field.

6.30 p.m.—Subscription Dinner, open to all who attend the Convention or Exhibition. (Will announce place later.)

SATURDAY, May 27—The **Exhibition** of the Foundry & Machine Exhibition Company will be open throughout the day and evening. Exhibition open daily, May 29 to June 1.

Convention Executive Committee.

W. B. Robinson, Press.

LARGE STEEL CASTINGS.

By Kelpie.

A few weight particulars of steel castings used in the construction of the White Star steamships "Olympic" and "Titanic" will doubtless be of interest to readers of Canadian Foundryman. The stern frame, of special quality mild steel and weighing 70 tons, is of hollow or dished section in two pieces 63 and 37 feet 4 inches long respectively. In casting the main piece of it, nearly 95 tons of molten metal were brought into service. The after cross arms weigh 74 tons, the forward cross arms 45 tons, and the rudder 100 tons.

YELLOW BRASS MIXTURE FOR PLUMBERS' BRASS GOODS.

For high steam pressure yellow brass does not give good results, and cannot be used. It leaks and becomes brittle at such a point, and is not sufficiently non-corrosive for some kinds of work. A red metal, therefore, is necessary for such work. For plumbers' brass goods, such as faucets and cocks, or similar work, yellow brass can be used to a good advantage in spite of opinions to the contrary, and is much cheaper than red metals. Some manufacturers maintain that although a yellow brass mixture is cheaper than a red one, the castings made from it are practically no cheaper than those made from red metal on account of the greater percentage of loss; but this has not been found true in practice, and evidently has been brought about by the use of a poor mixture.

A yellow brass mixture for making plumbers' brass goods should not contain too much spelter, or the castings will contain dross, and leak. The following one has been found very satisfactory for such work, and is extensively used:

Copper	70 lb.
Zinc	25 lb.
Lead	3 lb.
Tin	2 lb.

The tin is necessary for producing the desired stiffness and hardness, and the lead will impart the free cutting qualities required in brass to be worked on automatic tools. Care should be taken not to exceed the quantity of lead given.

The preceding mixture, according to the "Brass World," will give hard, strong castings, and will cast soundly and run freely.

Description of the Doherty Process of Ironfounding

By Cupola

Being a Few Notes Taken of a Paper Read By W. A. Grocock, Toronto, at a Meeting of the Central Railway and Engineering Club Held in Their Rooms, Prince George Hotel, Toronto, on Tuesday Evening, 21st March, 1911.

MR. DOHERTY, the inventor of the process bearing his name, is a Canadian by birth, having been born in Sarnia, Ont. He has devoted the major portion of his lifetime to ironfounding investigation, with a view to determining if possible, some reliable data by means of which accurate results may be forecasted.

It is well known to all engaged in foundry work, that variation of quality is found in two or more sample castings under test, in spite of equal provision made by every determinable and known condition or circumstance, to have them alike.

Uncertainty of result seeks a remedy in the right amount of air at the blast, amount and suitability of fuel, melting

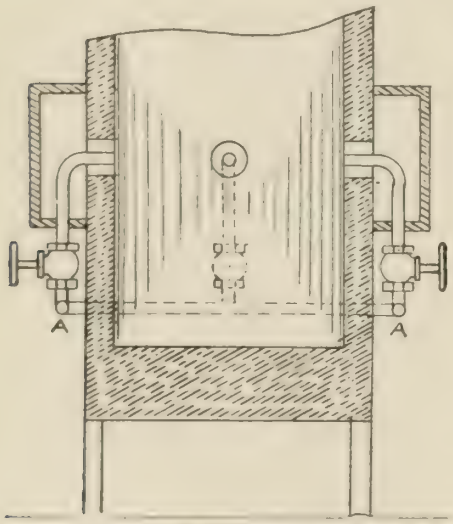

Fig. 1.—Lower part of Cupola with Doherty Process Attachment.

temperature and introduction of some other factor to co-operate with these, in dealing with the variety and physical composition of the mixture to be melted.

Explanation of Process.

In the Doherty process, the factor introduced is that of dry or slightly superheated steam. Referring to Fig. 1, the steam pipe A. A. is carried around the cupola as shown, and from it, ¼-in. branch pipes with regulating valves enter the blast chamber and are directed through each tuyere.

To prevent condensation, the steam piping is covered with non-conducting composition, and the pressure of steam used has been from 80 to 90 pounds per square inch.

Results Attained.

The effect of the steam jets is to generate hydrogen gas which absorbs and carries off the sulphur present, and thereby ensures a more homogenous, softer and stronger casting.

The presence of sulphur as is well known, contributes largely to the comparative weakness of castings. This feature of easy riddance admits of the use of materials for cupola purposes, more or less high in that element, and is simply a question of operation and jet regulation to deal with it in abnormal quantity.

It was also shown by Mr. Grocock that material for the melt, high in oxide gave a higher return in iron cast by the Doherty process than was ordinarily attainable. In other words less oxide went to slag, and more of it was saved.

Further beneficial results claimed for the process, are a cleaner and longer life to the furnace, with the practiability of the use of scrap of immaterial quality and quantity.

Personal Experiences.

On assuming charge of the foundry of a bridge works at Garston, Liverpool, England, Mr. Grocock was informed that this department showed a loss of $5,000 for the year previous. With a commendable confidence in himself and the Doherty process, which by the way, he had successfully operated in Rangoon, British Burmah, Mr. Grocock set himself steadfastly to make good.

That he and his process succeeded is borne out by the following results. The $5,000 loss was turned into a $7,500 gain, realized by an output increase, which gradually developed until the corresponding twelfth month showed an increase of 160 per cent. Factors conducing to the achievement were the reduction of wasters from 18 to .9 per cent. and back scrap from 40 to 8 per cent.

The metal produced, approached closely to that of malleable cast iron, being uniform, close grained and silver grey in color. Test bars from it showed with a load of 3,360 pounds on centre, a permanent set of 1 inch without fracture.

Costs and Opinions of Users.

The Doherty process involves an extra percentage of limestone for flux purposes being added, but the additional expenditure in this respect is limited to about 1 cent. per ton.

Cupola and machine shop savings have been shown to amount to $4 per ton. A superior casting free from that hardness which worries and increases cost of machine work, is by the Doherty process attainable.

Among different concerns using the system may be instanced the Goldie & McCulloch Co., Galt, Ont. Their commendation or appreciation is to be found in the fact that their experience has been satisfactory. They have found that more scrap and less pig iron can be used, and that the casting is softer, tougher and stronger. Permanent adoption of the process has been made by them.

The discussion of the subject by various members at the close of the paper elicited the information that the process has been in use off and on for about 10 years, and that its adoption has not been as general as might have been expected due to the fact perhaps that

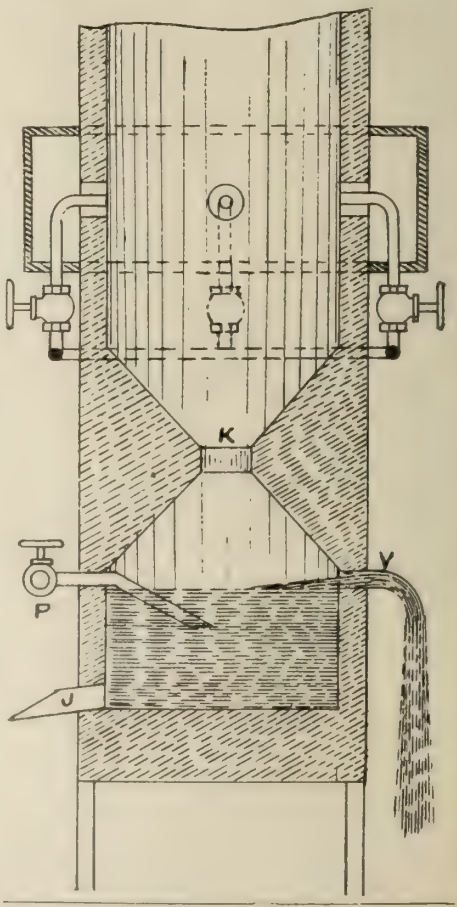

Fig. 2.—Lower part of Doherty Iron and Steel Cupola.

scrap, to which it has special application, is something like $1 per ton dearer than pig iron.

Combined Iron and Steel Cupola.

Fig. 2 shows the latest Doherty invention; a combined iron and steel cupola which has for its aim the conversion of molten iron into steel, suitable for machinery purposes to which cast iron is at present generally applicable.

The upper portion of the figure is equipped with the Doherty process as in Fig. 1, and is used for melting the iron. The bottom of the chamber is coned to form the neck K, through which the molten metal passes to the lower chamber. Here, compressed air is blown into and under the iron by means of the connection P, the effect of which is with proper regulation to convert the metal into steel of any desired constituency.

The slag is drawn off at outlet V, and the resultant metal at J.

Mr. Grocock treated the whole subject with the confidence of one who knows the ironfounding business thoroughly, and his commendation of the "Doherty Process" was marked by sincerity of belief in its superiority over the ordinary method.

BRASS MELTING FURNACE.

By Fettler.

The sketch fig. 1 shows in detail the arrangement and equipment of a useful furnace for melting brass and alloys of a like nature. Its principal dimensions internally are 15 inches square by 28 inches deep. The flue hole is 10 by 7, the chimney 10 inches square inside and at least 15 feet high.

It is built of ordinary brick, lined with firebrick, and has front fire-bar bearer moveable, to permit of its sliding forward and allow the bars to drop down as required.

Such a furnace will melt 80 pounds of metal quickly and easily.

The tongs for pouring the metal are shown at A, and those for lifting the crucible off the fire at B.

The Melting Process.

The following is a description of the melting process. The crucible is placed over the fire, upside down until properly heated. When this has been effected, it is turned right end up, made to rest with its bottom on a firebrick clear of the bars, and packed round with coke to steady.

Copper cut into small pieces is then placed in the crucible and melted, after which tin is added, melted and mixed.

To test the proper casting heat, a piece of zinc is dropped into the crucible. If it flares up at once the metal should be poured, if not, the proper casting heat has not been reached.

Previous to pouring, the dirt and rubbish is skimmed off the surface of the molten metal.

As soon as the metal is poured into the mould, the moulding boxes are opened and the castings sprinkled with water to ensure quick cooling. Quick cooling leaves the metal softer and more uniform than if slowly cooled. Further, the metals forming the alloy have a tendency to separate, and as a consequence

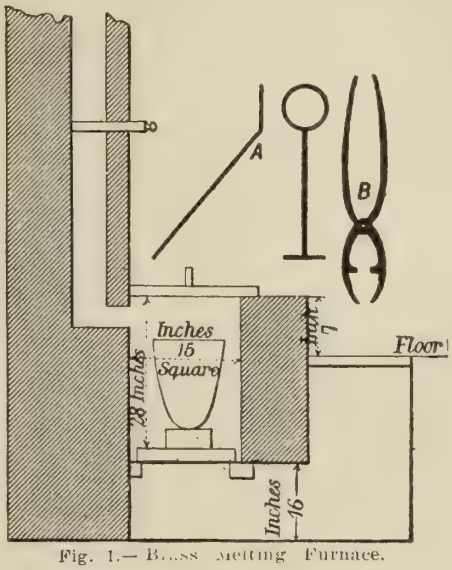

Fig. 1.— Brass Melting Furnace.

the heavier would be found at the bottom of the mould.

In melting old brass, the addition of tin may be unnecessary, although a small addition of zinc is found beneficial.

When a mixture of part old brass and part copper is melted, tin should be added in proportion to the new copper, and zinc in proportion to the old brass.

The strength of the metal varies considerably, and depends to a large extent on its manipulation both in the crucible and in the casting.

MOTOR TRUCKS IN MANUFACTURING TRADES.

By K. Campbell.

HANDLING an output of a factory, receiving raw material and moving machinery around the plant and yard is often done at a great inconvenience in some plants. If they are not adjacent to a railway nor fully outfitted with yard cranes, it is rather inconvenient and sometimes costly to handle the materials used in the plant or shipped from it.

It would be possible to pick examples of work of self-propelled trucks in almost every line of manufacture. Many forms of bodies have been designed to facilitate the rapid loading and unloading, with the object of keeping the machine actually running as many hours in the days as possible, on the same principle that every factory manager keeps his machinery constantly in operation to increase the earning capacity of the investment.

The market affords power trucks of every capacity, from one ton to ten tons, with speed limits of from five miles to fifteen miles an hour, loaded. There is every possible choice for the purchaser in the matter of power, type of engine or battery, form of transmission and final drive, in tire and other equipment and in price.

Almost any motor truck can do the work of three or more waggons and the necessary teams to haul them, and there are many services in which they are proved by records to be doing several times this proportionate amount of work, with all the saving that this represents.

Figures carefully compiled by The Gas Engine show that ten three-ton gasoline trucks, all covering forty miles a day and operating 300 days a year, can be maintained and operated at an average daily cost per machine of $9.75. The items contributing to this average are as follows:

Fixed Charges Per Year on One Truck.	
Interest, at 6 per cent on $3,000, cost price	$ 180.00
Depreciation, at 20 per cent.	600.00
Insurance, at ½ per cent.	15.00
Storage, 200 sq. ft. at 50c.	100.00
Total	$ 895.00
Add 20 per cent. for two spare machines	179.00
Total	$1,074.00

Dividing by 300, the number of working days in the year, this gives $3.85 per day.

Running Expenses Per Day for Ten Trucks—	
Wages of ten drivers at $2.50 for ten hours	$25.00
Wages of repairman, helper and washer	7.00
Gasoline, 80 gallons, at 12c.	9.60
Lubricants, at 1c per mile	4.00
Maintenance, at 10 per cent a year	10.00
Superintendence	3.20
Incidentals—light, heat, tools, waste, etc.	2.87
Total	$61.67
Average running expense per truck	6.17
Fixed charges per truck per day...	3.58
Total maintenance and operating ing cost	$ 9.75

Calculated in the same way, it is shown that a service of ten five-ton trucks can be operated at an average daily cost per vehicle of $11.48.

Such figures can only be taken as a fair guide to the probable cost of an installation. They are, if anything, rather high in the light of results obtained by some users, but conditions of work, usage and care vary so much with different installations that no figures can be applied to all.

MELTING IRON IN CRUCIBLES.

By W. J. May.

The cupola is generally used on account of its cheapness in melting iron; from 10 to 12 pounds of good coke melting 100 pounds of iron against 50 to 100 pounds of coke being required for the same melt in a crucible furnace with ordinary draught.

With an ordinarily well-built furnace from forty to sixty pounds of coke would be used, according to whether early or late fires are being dealt with, the latest melts naturally using less fuel than the earlier ones; but even with a ten-hour day during which perhaps seven melts are obtained, the average consumption of coke will be close on fifty pounds of foundry coke per hundred weight of metal melted.

With coke at $10 per ton this means that cupola melting costs 6 cents per hundredweight of metal, while crucible melting costs 25 cents per hundred. weight for fuel alone.

Against this there is generally a better class of metal obtained and the iron thus melted is cleaner, and produces better castings owing to its picking up practically no impurities during melting. Still, unless the work done is especially particular, it scarcely pays to expend so much on melting. If we have badly built furnaces, we get larger fuel consumption and much slower melting, with of course, increased costs.

Furnace.

Carr's patent crucible furnaces when properly fixed will be found to give better results than the built furnaces; but these often prove expensive in fuel if the flue and chimney part of the business is badly designed; for while as furnaces they are better than the others they still need the chimney arrangement to be good, or they will eat up fuel.

All natural-draught furnaces depend on the chimney and connecting flues for their efficiency, and it is useless to alter the furnace when the chimney is at fault.

Where economy is considered, a 400 lb. Morgan tilting furnace of the A or D type would give the best results both in first cost and in melting. Soft grey iron takes only about twenty-eight pounds of hard coke per hundredweight of iron on an average with a full day's work, provided there is electricity or some other available motive power at command. There is no chimney or expensive pit to build, but only an iron flue-pipe to convey the products of combustion outside the workshop.

Probably only small castings comparatively would have to be cast in a works foundry of small size, the large castings being brought in from outside, and this would mean that a portable furnace which needs no deep pit, and in addition no expensive chimney, would be more economical in all ways than the usual form of built furnace.

In most cases there would be a saving in crucibles as well, because in the Morgan furnaces the crucibles are fixed in position, and need renewal only when worn out in the actual melting work, and are not, as is the case with ordinary furnaces, knocked to pieces with the tongs and other tools, which are very often badly fitting and altogether too roughly made.

The great point in fitting up a foundry for crucible melting is to ensure a moderate cost for melting and repairs, and to do away with large primary outlay.

The ordinary-built furnaces are cheap enough in themselves, but if to the cost of the furnaces and pit is added the cost of chimneys, then the sum total becomes a large one, and compared with the cost of one or more Morgan tilting furnaces to provide the same output of molten metal, probably there will be but a slight difference.

If the value of the tilting furnace as a salable asset be taken at any time the balance will be in its favor. A brick chimney has little value if pulled down, but a mechanical furnace always has a value according to its state of preservation.

Whatever furnace is used, care should be taken that it is efficient and as economical in working as the type selected will allow, while the very greatest care must be taken that the accessories required for the proper working of the furnace shall be as efficient as the furnace itself.

Proper lifting apparatus should be provided where the crucibles have to be lifted from the furnace, and this may be simply a block tackle running on an I beam, or some more complicated arrangement as the case may warrant; but in any case a straight vertical lift from the furnace should be made to avoid damage to the crucibles. The economical use of labor is as important as is the economical use of fuel; the question of expenditure in any foundry being of importance.

Fuel.

Besides the furnace and its accessories the fuel used is of considerable importance; a clean, hard coke being more effective than a dirty soft one. Besides the texture of the fuel, its ash content and the question of sulphur has to be considered, for a coke high in sulphur is injurious to the crucibles, and causes their rapid reduction to a useless state.

Gas coke is an expensive fuel for crucible work owing to its unequal composition, structure, and usually high sulphur content, and if the work actually done with this fuel were compared with what is done with an equal weight of hard furnace coke, it would drop out of use quickly, although the price per ton be comparatively low.—Mech. World.

MISCELLANEOUS ALLOYS

By Crucible.

The product of a brass foundry excels in variety of composition that of its iron or steel substitute, due perhaps to an ornamental as well as a practical use being made of it.

Gun metal

Where toughness and durability are wanted as for bearings and general castings, no better alloy than gun-metal is available. The proportion and constituent parts when required to be hard and tough, are copper 88, tin 10, zinc 2, giving a tensile strength of from 28,000 to 30,000 pounds per sq. inch.

For a softer and less strong metal, 2 parts less of copper and 2 additional of lead are used.

Sound castings with small shrinkage and not subject to corrosion are other prominent features.

Size and rate of cooling of casting, skill in properly mixing the various metals, ventilating the molds and relieving the cores, all conspire to affect the ultimate strength. Large castings have usually less strength than small ones, due to the fact that they almost of necessity must cool slower.

Phosphor Bronze

Phosphor bronze is composed of copper and tin with about ½ per cent. of phosphorus.

It is harder than ordinary gun-metal, very close grained and of about 35,000 pounds per sq. inch tensile strength. When heated, it is liable to crack. Much care should be exercised in melting and pouring it, and repeated melting depreciates its virtue.

Manganese Bronze

Manganese bronze is in composition similar to the two grades of gun-metal already referred to except that a small proportion of ferro-manganese is added.

It is largely used for propeller blades and is rolled into rods for various mechanical and commercial services.

Propeller blades as ordinary cast, have with it an ultimate tensile strength of about 49,000 pounds per sq. inch. If cast on end, however, and with a head of 2 feet or more, slightly better results will be obtained.

The strength of the rolled rods varies from 63,000 eo 72,000 pounds per square inch ultimate tensile strength.

Moffitt & Irving have applied for 3 1-5 acres of Ashbridge's Bay, Toronto, to erect a steel foundry and smelter.

R. J. Cluff, general manager of Steel and Radiation, Ltd., is preparing to erect the first building of their new plant in St. Catharines. This building will be 120x240 ft. and will cost $100,000

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Foundry and Machine Shop.

GALT, ONT.—The Canadian Tap & Die Co. intend adding considerable new equipment to their plant in the near future.

MONTREAL, QUE.—F. Driscoll has succeeded in interesting a number of Montreal capitalists in the Herbst Full Light Moving Picture machines and a company has been formed with a capital of $100,000 to manufacture and sell the machines which permit of motion pictures being shown without the extinguishing of the lights in a theatre.

LONDON, ONT.—The C.P.R. will spend $500,000 on a new 22-stall round house, new station yards and car shops in this city.

CARGILL, ONT.—Mr. McGillivray, of Brockville, is promoting a company which is establishing a windmill and iron pump factory here.

LONDON, ONT.—A large American steel industry with a capital of from $20,000,000 to $30,000,000, may establish a branch in London.

PORT BURWELL, ONT.—The C.P.R. propose spending $30,000 here on a round house, elevator, etc.

GUELPH, ONT.—Cowan & Walker have been awarded the contract for the new factory of the Canada Gate Co., a branch of the Iowa Gate Co., of Cedar Falls, Iowa.

CAMPBELLTON, N.B.—The machinery for the equipment of the new I.C.R. repair shop is now fully installed and many machinists and repair men have been recalled from other shops along the line.

PORT ARTHUR, ONT.—It has been announced here that the Greig Co. will commence work on their new plant as soon as possible.

TORONTO, ONT.—The C.P.R. has placed orders for about $3,500,000 worth of steel rails. The greater part of this order went to the Lake Superior Corporation, and the balance to the Dominion Iron and Steel Co. In addition to this, the railroad company is still in the market for about 20,000 tons of rails, which will bring its orders for the present year considerably over those for 1910. The C.N.R. has already placed orders for 90,000 tons, and before its construction programme is filled for the year, this amount will be more than doubled.

MEDICINE HAT, ALTA.—Following the announcement that the Lucky Jim smelting works would locate here, comes the news that this city will also get a wire nail factory, a glass works, an artificial stone and marble industry and a foundry and machine shop. Sites have already been selected for the Alberta linseed oil mill and the Alberta iron roller mills.

HAMILTON, ONT.—As a sequel to the numerous reports published that the plans of the Oliver Chilled Plow Co. depended to a certain extent upon the present reciprocity negotiations, the president, J. D. Oliver, has issued a flat denial of the same and expresses his regret that the company's name should be dragged into politics.

SYDNEY, C.B.—The new ammonia plant at the steel works is partly completed and the whole will be in operation in about a month. The best which the old plant has been able to do is thirteen tons. Twenty-seven tons will be possible with only half of the new plant in operation. Only one generator will be at work each day.

VANCOUVER, B.C.—The big plant of the Quesnelle Hydraulic Gold Mining Co., on Twenty Mile Creek, Cariboo District, which will sift the bed of the Cariboo River will be completed and go into commission next August. It cost upwards of $1,000,000.

NORTH VANCOUVER, B.C.—The Department of Public Works, Canada, has awarded McDougall-Jenkins, Engineers, of North Vancouver, a contract to build a steel tug for use in Victoria Harbor. The type of engine will be inverted fore and aft compound surface condensing, with a high pressure cylinder 15 inches and low pressure cylinder 34 inches diameter, stroke 24 inches, back columns of cast iron, front columns of solid round steel, to be equipped with steam reversing gear. Engines to be built by Ross and Duncan, Glasgow. The boiler is to be of the Scotch Marine type, single ended, 12 feet internal diameter at largest course by 11 feet long inside. Working pressure 150 pounds per square inch. There are to be three Morrison corrugated furnaces 36 inches mean diameter. Total cost will be $45,000.

PORT ARTHUR, ONT.—When the Imperial Construction Co. finish work on the new C.N.R. hotel they will commence the erection of the plant for the enamel works at Bare Point. It is also stated that they have the contract for the Port Arthur Wagon Works.

SARNIA, ONT.—The Imperial Oil Co. are building a new boiler shop, engine room and blacksmith shop here. Additional improvements will also be made during the year.

WELLAND, ONT.—The Electro Metals Co. are preparing to double the capacity of their plant here.

HAMILTON, ONT.—The Oliver Chilled Plow Works, have awarded the contract for the erection of its assembling building, amounting to $200,000 for the bulk contract, to H. C. Christman & Co., South Bend, Ind. The Hamilton Bridge Works Co. has the contract for the structural steel required. They will soon ask bids for the erection of a large malleable and gray iron foundry here.

HALIFAX, N.S.—The Scotia Foundry Co., a new concern, have purchased from Ald. Hoben, his store, factory and foundry, and are remodeling the premises. F. H. Stuart, for many years asociated with Ald. Hoben, is the promoter and secretary of the new company.

PRINCE ALBERT, SASK.—A large number of prominent citizens were present at the Prince Albert Foundry recently, when the first castings were turned out from that iron manufactory. Some months ago the city council entered into an agreement with W. McDonald to purchase castings made by him if he would establish a foundry here. This Mr. McDonald has done, and in partnership with him is Mr. Fraser. The foundry is now a going concern and is already receiving a liberal patronage.

NEW YORK.—The Pennsylvania Steel Co. has booked orders for 200 tons of rails for the Canadian Pacific Railway, which is also in the market for three small bridge spans.

MEDICINE HAT, ALTA.—The C.P.R. has been instrumental in securing the removal of the plant of the Lucky Jim Smelting Co. from Nelson to this city. Conditions here are much more favorable than in Nelson.

HANLEY, SASK.—The Hanley Iron Works are now under the control of Lee Bros. and were opened early last month. A full line of gasoline engines will be carried, including stationary, portable and tractors, and also a line of automobiles.

TORONTO, ONT.—The Canadian Northern Railway has so far this year, placed orders for 90,000 tons of steel rails for delivery this year. These will cost about $3,000,000. A great proportion of the rails came from Sydney, C.B. These will be laid in Ontario and the Prairie Provinces.

PORT MANN, B.C.—The C.N.R. and the British Columbia Steel Corporation are arranging the details for the latter's big steel plant to be erected here. Water power will be generated on a large scale and a great deal of the smelting will be carried on by electricity. The corporation has secured coal and iron deposits within a radius of 30 to 60 miles of the plant. The plans and estimates of the United Engineering and Foundry Co., Pittsburg, Pa., have been adopted for the proposed plant.

HESPELER, ONT.—The Hall-Zryd Foundry Co., of Grimsby, will locate here and carry on the manufacture of stoves.

MONTREAL, QUE.—The C.P.R. has ordered two huge steam shovels from the Montreal Locomotive Works, and are in the market for steel for three small bridges which are being built this year in connection with the improvements going on all over the company's lines.

HALIFAX, N.S.—The city has approved of legislation in regard to concessions to the Nova Scotia Car Works and to Moirs, Ltd. The Nova Scotia Car Co., successors to the Silliker Car Co. get 20 years exemption from taxation, the loan made to the Silliker Co., five million gallons of water free annually, and the rest at the rate of 7½ cents per thousand gallons, and less if the extra amount used is great enough to qualify for the lower rates. Moirs, Limited, get 20 years exemption of their entire equipment over and above $6,500. It is said to be the intention of this company greatly to increase its plant.

PORTAGE LA PRAIRIE, MAN.—The Canadian Corrugated Pipe Co. will this year make improvements to their factory and instal machinery which will increase the output more than four-fold.

VANCOUVER, B.C.—The C.P.R. has awarded a contract to Digby & Grenier, contractors, of Fernie, for the construction of a large bridge over the Old Man River at the south fork, near Fernie. The bridge will be 860 feet in length and 137 feet high, and will require 1,500,000 feet of timber, 1,000 yards of concrete, 500 piles and 2,000 yards of excavation. It is stated that its construction will occupy the greater part of six months.

The Shaft Bearings in

STEPTOE SHAPERS

never wear out. They are provided with bushings that can easily be replaced if necessary, and Ring Oilers keep the bearings constantly flooded in oil, thereby preventing the shafts from getting hot and cutting. The Bull Gear bearing has a chain oiler, and a number of other features (which we cannot explain here) make STEPTOE SHARPERS "just a little better."

The Cushman Chuck Co.
Hartford, Conn., U.S.A.
Established 1862

KINGSTON, ONT.—The K. & P. Ry. are planning extensive improvements this year. They will repair and renew about thirty-five small bridges and culverts and put in six or seven thirty-inch and thirty-six-inch concrete pipe culverts, erect three small steel girders, and two six-foot concrete arch culverts and four rail top concrete culverts. The company will also install a pillar crane for handling coal at Renfrew.

VANCOUVER, B.C.—The C.P.R. are calling for tenders for the construction of a new ten-stall addition to the engine house in the False Creek Yards.

BURNABY, B.C.—The Sumner Iron Works Co. are about to start the construction of their new works here. They will manufacture machinery, especially saw mill and shingle mill plants.

CALGARY, ALTA.—The new freight yards and round house of the C.P.R. have been put in operation. The round house is a modern structure, and will accommodate a very large number of engines.

ST. PHILOMENE DE FORTIERVILLE, QUE.—The business of B. Adelard, manufacturer of threshing machines, was badly damaged by fire recently.

OTTAWA, ONT.—Latham and Groves, machinists, have been succeeded by Latham & Co.

EXETER, ONT.—The Connor Machine Co. have obtained a charter.

WINNIPEG, MAN.—The Dominion Bridge Co., of Montreal, have made several large additions to their works here. The capacity is now placed at 18,000 tons per annum. An up-to-date engineering and draughting office has also been established.

MEDICINE HAT, ALTA.—The C.P.R. will spend $430,400 for improvements in Medicine Hat this year. The itemized table is as follows:—Extending station, $29,000; double tracked steel bridge, $314,000; extending switching yards, $60,000; new boilers in machine shops, $11,400; new station at Redcliff, $5,000; trackage west of city, $5,000; and gas connection and light for Dunmore yard and fencing of terminal, $6,000.

PORT HOPE, ONT.—The International Tool Steel Co. have let the contract for their new factory to McGreggor & McIntyre, of Toronto, to be completed by May 1st. There will be three buildings, one 160 x 60, another 62 x 30 and a third 30 x 30, all of structural steel.

WELLAND, ONT.—Work on the addition to the plant of the Page-Hersey Tube Mills has been commenced. The increased factory will employ between two and three hundred additional men.

TORONTO, ONT.—The Ontario Brass Rolling Mills has changed its name to Brown's Copper and Brass Rolling Mills.

WOODSTOCK, ONT.—The Linderman Machine Co. have orders enough on hand to keep the factory going full speed for weeks, and these orders have been sent in voluntarily, without any soliciting.

WOODSTOCK, ONT. The Maximilian Tool Co. have their hammers on the market.

WINNIPEG, MAN.—G. Gale & Sons, manufacturers of iron and brass bedsteads, have purchased a site and will erect a $50,000 factory here.

MONTREAL, QUE.—Fire did $150,000 damage to the iron bed and stove foundry of the H. R. Ives Co., here, recently.

TORONTO, ONT.—Moffatt & Irving, a steel and iron firm, are trying to secure a five-acre site for a big steel and iron foundry in the Ashbridge's Bay district.

FALSE CREEK, B.C.—The C.P.R. are calling for tenders for the construction of a new ten-stall addition to the engine house. Construction will commence soon and it is the intention to have the building completed early in July. Ten old stalls are to be demolished to make way for the new addition.

CALGARY, ALTA.—Ten carloads of steel rails have arrived for the new street railway extensions. The rails are the first consignment from the Lorraine Steel Co., of Lorraine, Ohio.

PORTAGE LA PRAIRIE, MAN.—The C.P.R. are considering the building of a water softening plant here this year. The company has built a number of similar plants at points along the line.

PERTH, ONT.—An American syndicate has secured control of the car wheel works here. It is stated that the new owners can secure a contract of 200 wheels per day for five years. It is possible that the plant will be kept here, although Sydney or the Soo are also under consideration.

TORONTO, ONT.—It is reported that MacKenzie and Mann have purchased the patent rights for an invention that fastens steel

rails to steel ties. If this is true, these gentlemen evidently contemplate a complete change in their railway tie material.

THORNBURY, ONT.—The Reduction plant here will be enlarged and additional ovens put in.

Electrical News.

PORT ARTHUR, ONT.—The Ontario Hydro-Electric Commission will duplicate its plant at the hydro-electric station here to avoid any possibility of a general tie-up through want of extra apparatus. $11,200 will be spent for new equipment.

MAGOG, QUE.—Tenders will shortly be called for the construction of a large power dam on the river here. $125,000 will be expended on the dam and power plant.

SAULT STE. MARIE, ONT.—The Lake Superior Paper Co. will construct another power canal and a plant with a capacity of 40,000 h.p.

VANCOUVER, B. C.—The Vancouver Gas Co., subsidiary to the B. C. Electric Railway Co., will expend this year on plant, etc., about $600,000.

WINNIPEG, MAN.—Vickers, Sons & Maxim of Sheffield, Eng., to whom the contract for the electrical machinery of the new power plant at Point du Bois was awarded, are engaged in installing it. J. F. T. Thomas, of Sheffield, is in charge.

FORT WILLIAM, ONT.—The power plant of the Kaministiquia Power Co. will be increased to nearly double its present capacity.

PORT HOPE, ONT.—T. Garnett has accepted the contract to build the sub-station for the Seymour Electric Light & Power Co. The building will be 41x33, constructed of concrete, brick and steel, and will be finished May 15th.

CALGARY, ALTA.—The electric light by-law calling for an expenditure of $38,000 was carried by a large majority.

CALGARY, ALTA.—The power situation here has been cleared by the installation of a 900 horse-power machine at the Victoria Park power house, and additional machinery capable of producing 6,000 horse-power, including the Kananaskis hydro power. If the by-law for building the power extensions goes through this spring, an immediate start will be made with the building of the receiving and distributing stations for the hydro-electric power from Kananaskis.

ALBERNI, B.C.—The Alberni District Electric Light and Power Co. have been incorporated and in about a month's time will install fixtures and supply electric light in every home here. Arrangements have been made for the purchase of a steam engine and boiler, and the electricity will thus be generated until such time as the demand for light and power becomes large enough to justify the harnessing of water power.

SASKATOON, SASK.—The city commissioners have prepared the plans and specifications for the new electrical plant to be installed at the power house here this year. The cost is estimated at $60,000.

Municipal Notes.

TORONTO, ONT.—Tenders for the necessary plant for the construction of the new civic car lines are being called by the Board of Control. It will be modern and cost about $95,000. After the construction of the car lines, which will be about three years, the plant will be worth about $38,575, making the net cost $56,798. Tenders have already been called for the rails.

KERRISDALE, B.C.—The contracts for the laying of the pipes for the waterworks system in Point Grey have been awarded. The total amount of the tenders was in the neighborhood of $145,000.

CALGARY, ALTA.—The following expenditures have been authorized by the electorate: waterworks, $245,000; conduit, $60,000; paving plant, $20,000; incinerators, $120,000; fire hall, $75,000; sewers, $40,000, and electric light, $380,000.

BATTLEFORD, SASK.—A waterworks system is being installed here at an estimated cost of $100,000.

CRANBROOK, B.C.—The by-law calling for an expenditure of $100,000 for sewage purposes was defeated.

MEDICINE HAT, ALTA.—The city will spend $52,000 on sewers this year.

OTTAWA, ONT.—The city has been granted power to spend $400,000, of which $300,000 is for new sewage works, without submitting by-laws to the people.

ROSTHERN, SASK.—The municipality is securing estimates with a view to installing a waterworks and sewage system here.

SCOTSTOWN, QUE.—The municipality is considering the installation of a water and sewage system to cost $40,000.

VANCOUVER, B.C.—About $300,000 will be expended for sewer purposes and drainage.

NEW WESTMINSTER, B.C.—The Burnaby ratepayers are being asked to vote $300,000 on a waterworks system.

EDMONTON, ALTA.—A proposition to turn over to the city at the end of three years an equipment complete, capable of delivering at the corporation line, 20,000 horsepower of electrical energy from Rocky Rapids, on the Saskatchewan River, 60 miles from Edmonton, for the sum of three million dollars was made by the Edmonton Heat and Power Co.

LETHBRIDGE, ALTA.—The city will spend over half a million on local improvements this year. This includes appropriations as follows: sewer main extensions, $72,000; water mains, $100,000; storm sewer system, $41,000; and sewage disposal, $70,000.

TORONTO, ONT.—The city has awarded the contract for 27 rubber sleeves for the city's dredges to the Canadian Consolidated Rubber Co., their prices being $32.50, $25, $12.25 and $33 respectively, for 20-inch cast-iron pipe to the Canada Foundry Co., whose price was $39.95 per length.

CALGARY, ALTA.—The work of extending the new high pressure pipe line is now in progress. The cost is placed at $75,000.

FORT WILLIAM, ONT.—The city council has recommended the extension of the waterworks to certain localities at a cost of $750. They are also considering a proposition to install drinking fountains in this city.

HAMILTON, ONT.—This city has secured the necessary legislation enabling it to lay pipes for the purpose of distributing natural gas and selling it to the citizens. Wells, however, must only be bored within the city limits. As power to expropriate the Ontario Pipe Line plant was refused, the citizens will be asked to vote on the proposal to establish the civic natural gas plant.

HAMILTON, ONT.—The city has awarded the contract for the five new boilers at the Beach pumping plant to the Goldie-McCulloch Co., of Galt. This is only one of the large contracts to be filled by the big works.

NORTH TORONTO, ONT.—The ratepayers have authorized an expenditure of $265,000 to construct a sewerage system and to install disposal plants.

MOOSEJAW, SASK.—The city will spend, this year, $175,000 for sewer and water extensions and $50,000 for an incinerator.

MONCTON, N.B.—City Engineer Edington has estimated the cost of the proposed waterworks system at $250,000.

WELLAND, ONT.—Tenders are being called for the construction, etc., of one unit water-driven waterworks pumps, etc.

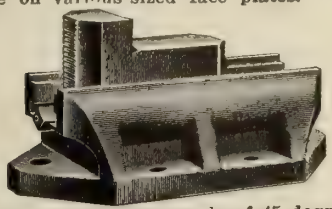
New Companies.

MONTERELLO, QUE.—The Owens Lumber Co. have been incorporated to acquire and operate saw mills, planing mills, etc., etc.

MONTREAL, QUE.—The Montreal General Contracting Co., capitalized at $200,000, have been incorporated. They will manufacture and deal in tools, implements, machinery, and erect iron foundries, machine shops, etc. E. G. Evans, civil engineer; R. Moffat, contractor; G. G. Hyde and W. G. Pugsley, advocate; and R. C. Grant, accountant; all of this place.

MONTREAL, QUE.—The E. Cantelo White & Co., have been incorporated to manufacture and deal in electrical fittings, appliances, etc. F. C. Reynolds, manager, Westmount, M. Alexander, advocate, D. Burley-Smith, clerk, R. Lloyd-Jones, manager, and T. H. Warren, bookkeeper, all of Montreal. Capital, $50,000.

MONTREAL, QUE.—The Eureka Damper Co. have been incorporated to manufacture and deal in stoves, furnaces, engines, boilers, etc. A. W. G. Macalister and C. M. Cotton, advocates, R. E. Allan, secretary, J. M. Mortle, student, and J. W. H. G. Hopman van den Berg, diamond merchant, all of Montreal. Capital, $60,000.

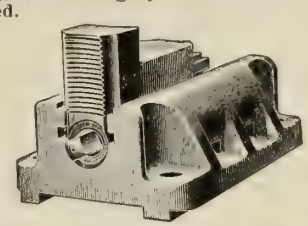


TORONTO, ONT.—The Fisher Electric Mfg. Co. has been incorporated and will manufacture and deal in electrical apparatus, supplies, etc., and carry on business of iron-founders, brass-founders, tool-makers, etc. F. C. L. Jones, barrister, L. W. Nurse, accountant, F. H. White, student-at-law, A. J. Peirce, law clerk, and E. M. Brown, stenographer, all of Toronto. Capital $250,000.

OTTAWA, ONT.—Morisset & Morisset have been incorporated and will manufacture and deal in machinery, implements, etc. L. C. Morisset, L. H. Morisset and M. A. Morisset, financial agents, A. R. Morisset and G. O. Morisset, civil servants, all of Ottawa. Capital, $100,000.

TORONTO, ONT.—The British Columbia Steel Corporation have been incorporated to manufacture and deal in iron and steel. W. Gilchrist, solicitor's clerk, A. M. Garden, W.

Face Plate Jaws



New features include extra large screws, double thrust bearings and special methods of attaching, permitting their use on various-sized face plates.

Ends pointed at an angle of 45 degrees so that four jaws will fit close together at centre. Sizes 4-in. to 14-in.

Boring Mill Jaws

As in the face plate jaws, screws are larger than usual, thrust bearings are double and jaws are wider, heavier and better supported. Made in all steel or with grey iron base as desired.

JOSEPH DIXON CRUCIBLE COMPANY
JERSEY CITY, ... N.J., U.S.A.

C. Davidson, and W. Lawr, students-at-law, and C. Y. Spearing, secretary, all of Toronto. Capital,, $10,000,000.

MONTREAL, QUE.—The Laurentide Co., capital $10,000,000, have been incorporated to erect, operate, etc., etc., pulp mills, factories, etc. R. C. McMichael, W. F. Chipman, and R. O. McMurty, advocates; F. G. Bush, bookkeeper, G. R. Brennan, stenographer, M. J. O'Brien and H. W. Jackson, clerks, all of this city.

TORONTO, ONT.—The Skeena-Naas Pulp and Lumber Co., capital $1,500,000, have been incorporated to own and operate saw mills, pulp mills, etc. W. Gamble, of Ottawa, barrister, H. B. Housser, financial agent, A. B. Taylor and S. R. Broadfoot, students, and L. Hull, clerk, all of this city.

MONTREAL, QUE.—The Standard Steel Works, capitalized at $1,000,000, have been incorporated to carry on the business of iron masters, steel makers, steel converters, iron founders, etc. G. V. Cousins and O. B. McCallum, barristers; P. F. Brown, secretary, W. R. Ford, clerk, and S. T. Mains, bookkeeper, all of this city.

OTTAWA, ONT.—The Power Specialties, Limited, capital $50,000, have been incorporated to carry on a general foundry and machinery business and to manufacture and deal in furnaces, boilers, stoves, ranges, etc. J. K. Paisley, hotel proprietor, F. W. Bendon, agent, G. H. Bendon, manufacturer's agent, G. W. Sequin, city collector, and L. Blackmore, agent, all of this city.

Planing and Saw Mills.

VANCOUVER, B.C.—The B. C. Lumber Co., a $20,000,000 concern, will erect a saw and pulp mill on their Massett Island property, and contemplate the erection of two large mill plants on the southern mainland.

CORDOVA, ONT.—Ryan & Lynch's sawmill was totally destroyed by fire. The loss will amount to about $1,300.

RODNEY, ONT.—The sawmill and lumber yard of Wm. Flater & Co. were completely destroyed by fire recently.

MASSETT, B.C.—It has been announced here that L. C. Christie, of Ladysmith, is interested in a proposition to construct pulp mills on the Ain river, Graham Island, and open up sawmills in the vicinity.

PRINCETON, B.C.—McDougall & Waddell have completed arrangements to operate a sawmill on Onemile. It is understood the B. C. Cement Co. will require half a million to use in construction work.

VERNON, B.C.—W. H. Magee, of Vernon, who has been operating a sawmill at Lumby for a number of years, has made arrangements to operate the Ruth & Turner mill at Canoe Creek, during the summer.

GALT, ONT.—Plested & Parker have about completed their new planing mill here and will make sashes, doors, etc.

FORT GEORGE, B.C.—The Peace River Lumber Co., an American syndicate, will erect a sawmill here.

ABBOTSFORD, B.C.—The Abbotsford Timber & Trading Co. are opening up a lumber yard and mill here. They will also erect a large warehouse and office building.

REVELSTOKE, B.C.—The Deamond Mills Co., of this place, will erect a sawmill near Arrowhead.

WINNIPEG, MAN.—A Winnipeg syndicate, headed by J. D. McArthur, railway contractor, has acquired the assets of the Fort George Lumber & Navigation Co., which recently went into liquidation. The holdings include two sawmills at South Fort George.

HESPELER, ONT.—W. A. Kribs is enlarging his planing mill, sash and door factory here, and installing additional machinery.

NELSON, B.C.—Waters & Pascoe have opened up their new $10,000 sash and door factory here.

MOOSE JAW, SASK.—The Western Manufacturing Co., Regina, has purchased the Saskatchewan Sash & Door Co. here and has spent $10,000 improving it. Included in the improvements was the addition of modern machinery for the manufacture of sash, doors, mouldings, frames and turned work, store and office fixtures.

Building Notes.

VANCOUVER, B.C.—The Vancouver Hotel will build an annex, at a cost of $190,000.

PRINCE ALBERT, SASK.—A, Lunn, of Asquith, Sask., will build a large hotel here, at a cost of $100,000.

SASKATOON, SASK.—Storey & Van Egmond, of this city, have prepared plans for a six-storey departmental store building here.

NEW WESTMINSTER, B.C.—The Westminster Trust Co. will erect a ten-storey building here. Only six storeys will be erected at present.

CALGARY, ALTA.—Plans have been prepared for a six-storey block for F. Fairey. The cost will be about $300,000, and it will contain stores, offices and apartments.

SASKATOON, SASK.—J. I. Case Co., the big threshing machine manufacturers, of Racine, Wis., have secured a site upon which to erect one of the largest warehouses in the city.

MONTREAL, QUE.—E. H. Ford, Canadian manager of the Ford Iron Co., and representing an English syndicate, has announced that they will spend $1,250,000 in building summer hotels at Montreal, Toronto, Winnipeg, Ottawa and Vancouver.

VANCOUVER, B.C.—Architect Hooper prepared the plans for a four-storey labor temple, to cost $143,000. The building, planned to be 75x120 feet, will have reinforced concrete and brick curtain walls. The Norton-Griffiths Steel Construction Co. have the contract.

TORONTO, ONT.—It has been estimated that an additional $300,000 will be spent on St. Alban's Cathedral here this year.

SASKATOON, SASK.—The city is procuring plans for a new city hall, to cost $150,000.

CALGARY, ALTA.—The Hudson's Bay Co. are building a big six-storey departmental store here, at a cost of $100,000

VANCOUVER, B.C.—F. Patrick, son of the millionaire lumberman, is promoting the erection of artificial ice rinks in the two coast cities. $200,000 will be expended in the buildings and plant here.

NEW WESTMINSTER, B.C.—The new Royal Columbian hospital will be built here this spring, at a cost of $175,000. Radical changes in the plans will probably necessitate the calling of new tenders.

SAULT STE. MARIE, ONT.—It is generally understood that the newly-incorporated Lake Superior Paper Co., capitalized at $8,000,000, will build a large paper plant here. They have purchased twenty acres from the Lake Superior Power Co. The land includes the buildings on it, which consist of the frame rear extension of the pulp mill, the sulphite mill, and the smelting and reduction works. The buildings are incorporated in the new works and will be used.

VANCOUVER, B.C.—The B.C.E.R. will erect a $350,000 building here. It will be strictly modern.

WEYBURN, SASK.—The M. D. McKinnon Co., intend erecting a large departmental block of brick structure with elevator and all modern conveniences.

HARRIS, SASK.—The Imperial Oil Co. will erect a warehouse and two large tanks at this point as soon as spring opens up. Wilson & Conway will be in charge.

ST. JOHN, N.B.—The contract for the construction of the foundation of the Atlantic Sugar Refinery Co.'s two million dollar plant at the ballast wharf has been awarded to The Foundation Co., Montreal.

VICTORIA, B.C.—H. S. Griffith, architect, has prepared plans calling for a mammoth structure ten storeys high to cost $1,000,000. It is planned to serve the purposes of a theatre, hotel, and office building.

FORT FRANCES, Ont.—The C.N.R. propose spending $200,000 on a summer hotel and grounds at Pither's Point, here.

General Manufacturing.

PERTH, ONT.—W. J. Winn has been engaged lately in installing the gas producer plant and a number of machines at his factory here.

ST. JOHN, N.B.—The Wilson Box Co. have successfully started operations at Fairville. The plant and lumber yards cover eight acres, while the box mill itself has 42,000 sq. ft. of floor space. The power plant is built of concrete and covered by re-inforced concrete roof, and contains two new tubular boilers of 125 h.p. each and a Corliss engine capable of developing 250 h.p., making a most complete steaming outfit; the fuel used being the sawdust and shavings from the different machines, which are all connected to a blower system, which conveys it direct to the boiler house.

MONTREAL, QUE.—Brunelle Co., manufacturers of washing machines, has been registered. H. Brunelle and A. Brunelle.

SYDNEY, C.B.—Alex. Cross & Sons, Glasgow, Scotland, will shortly erect here a big fertilizer plant. They have contracted with the Steel Company for the company's total output of basic open hearth slag, from which the fertilizer is to be manufactured.

EDMONTON, ALTA.—P. Burns, the meat packer, will build his big packing plant in Edmonton, instead of Strathcona. The plant will be large, with modern equipment.

WOODSTOCK, ONT.—A deal has practically been consummated looking towards the establishment in this city of a branch of the big packing firm of Libby, McNeill & Libby, of Chicago.

WEST TORONTO, ONT.—Gunns Ltd. are erecting a refinery here for cotton seed oil, the first of its kind in Canada.

NEW WESTMINSTER, B.C.—Fox Bros., of Nelson, will establish a big jam factory here.

WOODSTOCK, ONT.—The Woodstock Textile Co. have started manufacturing their goods.

KINGSTON, ONT.—It has been decided to remove the Richardson Mica-washer Works to Trenton, N.J.

CALGARY, ALTA.—The Western Agencies & Development Co. are promoting the establishment of a linseed oil factory here.

LINDSAY, ONT.—The Canadian Handle & Wood Turnings Co. have taken over the business of the Rider & Kitchener Co. and will commence operations about the middle of this month.

SASKATOON, SASK.—Cushing Bros., Ltd., have secured a site and will shortly establish a wood-working plant here. They have plants in Calgary and Edmonton.

ST. JOHN, N.B.—Work has been started on the new $2,000,000 plant of the Atlantic Sugar Refinery.

PETERBORO, ONT.—The Independent Tire Co. will likely locate here. They contemplate the erection of a three-storey factory, with $75,000 worth of machinery.

Trade Notes.

TORONTO, ONT.—The General Supply Co., with headquarters in Ottawa, have opened offices and warehouse at 119 Adelaide St., west, in this city. They will handle a full line of belts, mill supplies, etc.

The Sterling Lubricator Co., of Rochester, N.Y., announce the removal of their factory to Norwich, Conn., where their shops will be combined with those of the Uncas Specialty Co., the new combination to be known as the Sterling Machine Co.

National-Acme in Montreal.

The National-Acme Manufacturing Co., Cleveland, manufacturers of automatic machines and their products, have just completed the equipping of a new plant at St. Elizabeth and G.T.R., St. Henri, Montreal, and operations will be started in April. In the Montreal plant they will manufacture screws, nuts, bolts and special parts for automobiles, electrical apparatus and all parts that can be made from bar stock. The equipment consists of Acme Automatic Multiple Spindle Screw Machines. Stocks will be carried of cap and set screws, plain and castellated milled steel nuts, semi-finished nuts and milled brass nuts. Contracts will also be made for the manufacture of special screws, nuts, etc.

Dominion Steel Corporation Extensions.

During 1911, the Dominion Steel Corporation, Amherst, N.S., will carry forward a vast amount of new work in connection with extensions to the plant. Recently the company placed plans in the hands of the local contractors and asked for tenders for the construction of some eight buildings. These new structures are to be as follows: Machine shop, 120 x 130 feet; foundry and machine shop, 120 x 440 feet; boiler house, 120 x 160 feet; pattern shop, 60 x 200 feet; car repair and carpenter shop, 120 x 140 feet; warehouse, 60 x 200 feet, 2 storeys; oil house, 60 by 60 feet; round house, 230 feet diameter, about 16 locomotive stalls. All of these buildings will be constructed of steel and compressed brick. The outlay will be in the vicinity of three-quarters of a million dollars. The new general office will be another structure for erection immediately, and plans for this $100,000 edifice are now in course of preparation. This will be a separate and distinct contract from the list already noted. Besides the construction of these buildings, there is also to be undertaken in 1911 the

PATENT NOTICE

NOTICE is hereby given that the owner of Canadian Patent No. 117,439, dated March 23rd, 1909, for Combustion Engines, is prepared to grant licenses under section 44 of the Patent Act, upon a reasonable royalty, to anyone wishing to manufacture the invention covered by the above patent. For licenses and information apply to

establishment of a merchant bar and rod mill, two blast furnaces, probably about 75 more by-product coke ovens, before next new year: the completion of the new turbo-electric system, and several other new items of expansion may develop during the present year.

Canadian Tap and Die Co., Galt, to Enlarge Plant.

Edward Blake, Jr., of Wells Bros., manufacturers of taps, dies, etc., has now taken over the management of the Canadian Tap & Die Co., Galt. It is his intention to install new machinery and otherwise increase the manufacturing facilities. The Canadian Company will manufacture a full line of screw cutting tools and in addition will handle a line of Wells Bros. machinery and tools, including the Universal Tool and Cutter Grinder. Mr. Blake will also represent the Miller's Falls Co., of Miller's Falls, Mass., manufacturers of braces, chain drills, hand drills, bench drills, breast drills, automatic and ratchet screw drivers, chucks, hack saws, etc. A stock will be carried at the Galt factory.

Bolt Factory for Fort William.

Barnett-McQueen Co. are installing a plant on Christina St., Fort William, for the manufacture of bolts of all kinds. Oil will be used as fuel in the heating furnaces. It is intended to add later machinery for the manufacture of heavy bolts and rivets for construction work. About 20 men will be employed on the start.

Welland Machine and Foundries, Limited.

A meeting of the members of the syndicate who took over the Robertson Machinery Co.'s plant, appointed the following as officers of the concern, which will now be known as "The Welland Machine & Foundries, Limited." Directors: J. H. Crow, R. J. McCormick, D. D. Hooker, D. Ross, Wm. Edestrand. President, David Ross; vice-pres. Wm. Edestrand; sec.-treas. J. H. Crow.

Welland's Industries Expanding.

As previously announced in Canadian Machinery, the Page-Hersey Tube Works will materially enlarge and improve their Welland plant. The enlargement will probably cost about $150,000. The contract for the first work in this connection—the erection of a new business office—has been let to David Dick & Sons, contractors, work to be begun as soon as the weather will permit. This office will be a two-storey, fireproof brick structure, of handsome design, and will cost about $8,000. A galvanizing plant will be included in the additions to the works.

Dick & Sons have secured the contract for the plant of the Canadian Automatic Transportation Co., at $25,000.

It is reported that Canadian Steel Foundries which secured control of the Montreal Steel Co., Montreal and Ontario Iron and Steel Co, Welland, will build a blast furnace in connection with the Welland plant this year at a cost of $1,250,000. Iron ore will be brought to Welland by water and smelted into pig iron and steel. A large tract of limestone property, west of Port Colborne, is under option, and it is believed this is to supply limestone for the smelter. A warehouse and machine shop will be erected at once at a cost of $100,000. The plant of the Electro Metals will be doubled in size. The company have been exceedingly prosperous, and have found it necessary to have increased accommodation.

United Motors, manufacturers of automobiles, will erect a factory building the coming summer.

Quality Beds have let the contract for the construction of a brick addition 60 x 80 ft.

Book Review.

Engineering Index Annual—Published by the Engineering Magazine, 140 Nassau St., New York; size 6x9 ins., 500 pages. Price $2.

This is the fifth annual index devoted to engineering and technical publications in Europe and America. While by no means complete as far as Canadian technical publications are concerned, it is recognized as a very valuable reference book for anyone seeking information on any technical subject.

The articles indexed are first grouped under the general division of engineering practice to which they belong—Civil, Mechanical, Electrical, Mining, etc., and under these again they are sub-grouped according to the recognized special divisions of each field.

A new feature has ben introduced into the fifth index annual to make it easier and more convenient for the consultant to find the reference he seeks. This is the assembly of all catchwords under their classified arrangement in front of the book, so that all topics under any heading, which in the book may be scattered through several pages, are here condensed into a list of a column or less.

The Strength of Oxyacetylene Welds in Steel. By Herbert L. Whittemore, has just been issued as Bulletin No. 45 of the Engineering Experiment Station of the University of Illinois. This bulletin gives the results of an extensive series of tests to determine the strength which may be developed in welded joints made by fusing thin steel plates together by means of the flame of an oxyacetylene blowpipe. It was found that with careful manipulation such a welded joint may be expected to have about 85 per cent. of the strength of the plate material. Considerable information as to methods of manipulation of the oxyacetylene blowpipe and the proper regulation of the gases is also given in the bulletin. Copies of Bulletin No. 45 may be obtained gratis upon application to W. F. M. Goss, director of the Engineering Experiment Station, University of Illinois, Urbana, Ill.

Oxhydric Welding—32-page catalogue on coated paper, from the American Oxhydric Co., Milwaukee, Wis., describes and illustrates in a very interesting manner their system of cutting and welding. Numerous applications of the system are given, these being illustrated in a number of cases.

An Investigation of Built-up Columns Under Load, by Arthur N. Talbot and Herbert F. Moore, is issued as Bulletin No. 44 of the Engineering Experiment Station of the University of Illinois.

In the course of this investigation, laboratory tests were made on steel and wrought iron built-up columns, such as are used in bridges and other structures, to determine not only their strength, but also the way in which the compressive stresses vary over the cross-section of the channels or other component parts of the column and throughout its length. The amount of stress in lattice bars and its variation from bar to bar was also measured. The distribution of stress over the cross-section of a lattice bar was studied. Field tests were conducted on the columns of a railroad bridge under the load of a locomotive and train, and the distribution of stresses over various parts of the columns was measured. The investigation shows that the variations from the ideal column which result from shop and erection processes may be more important than the influence of length, and that on account of such causes the stress at one or more points in a column may be as much as 50 per cent. inexcess of the average stress. This investigation may be expected to have an important bearing on structural engineering practice. Copies of Bulletin No. 44 may be obtained gratis upon application to W. F. M. Goss, director of the Engineering Experiment Station, University of Illinois, Urbana, Ill.

Farwell Automatic Gear Hobber.—Circular 805 from the Adams Co., Dubuque, Iowa, 16 pages, 8½x11 ins., describes and illustrates the Farwell Gear Hobber.

Ajax Electric Riveting Machines—Catalogues are being issued by the Hanna Engineering Works, 2095 Elston Ave., Chicago, who have entered into a contract with the Electric Machinery Sales Co., Milwaukee. The light yoke riveters shown in one of the bulletins is said to be the first offered to the trade. Circular matter will be furnished by the Hanna Engineering Works on application.

Smooth-on—The Smooth-on Mfg. Co., Jersey City, N.J., have issued 16-page booklet describing their products, including cements, "Smooth-on" for castings, joints, packing, gaskets, paint, etc.

Flexible Shaft—Catalogue from the Bamridge Patent Flexible Shaft Co., British Engineering Works, Kettering, Eng., describes the Bamridge patent and illustrates many applications.

Decimal Equivalents—The Garvin Machine Co., Spring and Varick Sts., New York, are mailing on request a large hanger, 24x24 ins., containing decimal equivalents in sixty-fourths. The type is large enough to be seen from considerable distance.

Casehardening—W. H. Palfreyman & Co., 17 Goree-Piazzas, Liverpool, have issued a booklet on "Hints About Casehardening: What to Use, and how to do it." The booklet gives a fund of general information on the subject.

Discount List—S. A. Daniel, Birmingham, Eng., has issued an export discount list of tools.

Quick Threading Attachment—16-page catalogue, 9x12 ins., from the Hendey Machine Co., Torrington, Conn., U.S.A., describes the quick threading attachment for Hendey-Norton lathe.

THE NATIONAL TOOL CO.
CLEVELAND, O., U.S.A.

The Mechanical World Electrical Pocket Book. Size 4 by 6 in.; pages 208. Bound in cloth. Published by Emmott & Co., Ltd., 65 King Street, Manchester, England. Price 12 cents net. The 1911 electrical pocket book has been thoroughly revised and many new illustrations introduced. Among the particular changes noted are that the descriptive matter has been condensed, thus affording space for a larger number of new tables on subjects such as current densities, permissible temperature rise, percentage losses in electrical machinery, units of illumination, incandescent lamp current consumption, life of glow lamps and allowances for depreciation. The notes on accumulators have been rewritten and extended as well as the sections dealing with circuit breakers, boosters and the use of electricity in coal mines. Another change worthy of special mention is the introduction of a new section on liquid starters. In all sections, both the new ones and those which have been included in previous issues, considerable useful data and tabular information have been given.

Drop Forging, Die Sinking and Machine Forming of Steel—By J. V. Woodworth, published by the Norman W. Henley Publishing Co., 132 Nassau St., New York; 340 pages, 6x9 ins., 300 illustrations. Price, $2.50.

This is a practical treatise on modern shop practice, processes, methods, machines, tools and details, treating on the hot and cold machine-forming of steel and iron into finished shapes; together with tools, dies and machinery involved in the manufacture of duplicate forgings and interchangeable hot and cold pressed parts from bar and sheet metal.

This is the fifth dealing with forging, tempering, power presses, etc. This one is full of facts gleaned from various sources, such as the technical papers. The growth of die-sinking and machine forging has necessitated a standard work, which has now been prepared. The methods are described in plain language, which will be easily read and understood by those engaged or interested in this line of work.

CATALOGUES.

AIR COMPRESSORS—Catalogue 391 from National Brake and Electric Co., Milwaukee, U.S., describes National air compressors and accessories.

REFRIGERATION—"A profitable day load," is the name of a refrigeration bulletin No. 508, issued by the Triumph Ice Machine Co., Cincinnati, Ohio. A number of refrigeration outfits are shown.

FEED WATER HEATER—National Pipe Bending Co., 156 River Street, New Haven Conn. Booklet. Treats of the National feed water heater for boilers from 5 to 4,000 h.p., which consists of one or more coils of seamless drawn tubing inclosed in a cast iron or steel shell to which exhaust steam is admitted, heating the water as the latter passes through the tubing. Directions for erecting the heater and its use in condensing steam plants are included.

TRANSMISSION SUPPLIES—The Elmira Machinery & Transmisson Co., Elmira, Ont., have issued Catalogue B, in which a complete list of transmission supplies for engineers, founders and machinists, is listed. Among those manufactured by this company are power transmission appliances, wood split pulleys, friction clutches, couplings, hangers, etc. In addition, there are listed Cumberland turned and ground steel shafting, Chapman double ball bearings, leather, rubber, cotton and balata belting, etc.

WATER VALVES—A 4-page folder describing the hydrostatic water valve and its application, has been issued by the Cleveland Steel Tool Co., 660 East 82nd St., Cleveland, Ohio. The valve maintains automatically constant level in tanks, vats, heaters, low-pressure boilers, etc.

FRICTION CLUTCHES—The Dodge Mfg. Co. have issued a 16-page catalogue describing Dodge split and solid clutches. The economic features are dealt with and the construction of the clutch is given in detail. A two page table shows the sizes manufactured, together with full information in regard to h.p. transmitted, speed, face of pulley, cost, etc.

POLYPHASE INDUCTION MOTOR—Bulletin 126 from the Crocker, Wheeler Co., Ampere, N.J., discusses the induction motor and its application in textile mills, woodworking plants, etc. Many illustrations show these applications.

LAGONDA-ENTERPRISE MULTIPLE STRAINERS is the title of an attractive catalogue recently issued by the Lagonda Mfg. Co., of Springfield, Ohio. It contains a description of a new type of Multiple Strainer suitable for the removal of suspended matter, such as ice, sticks, seaweed, grit, etc., from boiler feed water, and also from condenser circulating water. These strainers are built in sizes up to 48 in., with a number of different compartments, depending upon the size. The Lagonda-Enterprise Strainer is unique in that its effective straining area is from 2½ to 6 times larger than the area of the pipe. It is also possible to clean separate compartments of the strainers without interrupting the flow through the others, thus eliminating the necessity of shutting down circulating or boiler feed pipes in order to clean out the filters used.

RUBBER VALVES.—Folder from H. W. Johns-Manville Co., 100 William street, New York, describes J-M rubber valves.

STEAM SPECIALTIES.—A 40-page catalogue for 1911 from Darling Bros., Montreal, describes and illustrates a number of lines manufactured and handled by them, including heaters, pumps, traps, valves, etc.

VOLUTE PUMP—Bulletin 106 from the John McDougall Caledonian Iron Works, Montreal, describes the Volute Pump and its applications.

PULLEYS.—Folder from Positive Clutch & Pulley Works, 11-13 Jarvis street, Toronto, describes the pulleys and clutches being placed on the market by them.

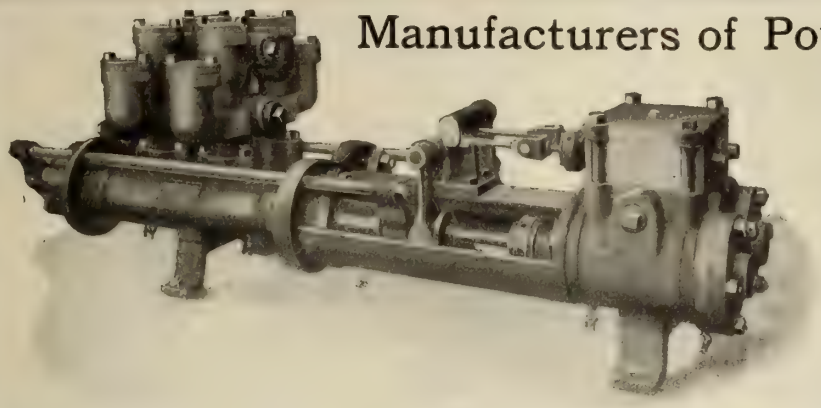
MECHANICAL LUBRICATOR. — Bulletin 53, 16 pages, 6 x 9 ins., from the Richardson-Phenix Co., Milwaukee, shows a number of installations and gives useful information regarding the operation of the system.

UNIVERSAL ELECTRICAL DIRECTORY By J. A. Berly, published by H. Alabaster, Gatehouse & Co., 4 Ludgate Hill, E.C., London, Eng.; 1,552 pages; price, post free, 14s 6d.; British, Colonial and General Sections only, 10s.

This eleventh edition has been as carefully revised as previous issues, and no pains spared to make it as accurate and reliable as ever.

The contents are divided into four sections: The British, with 13,590 names; Colonial and General, with 5,840 names; Continental, with 7,970 names; U. S. A., with 6,500 names; totalling 33,900 names, although unimportant entries are omitted. Each section is subdivided into alphabetical and classified sections, while in the case of the British a Geographical Section has been added, which is a necessity for all travelers. Any section can at once be referred to by means of a thumb index.

Telegraphic addresses, telephone numbers and codes are given in the alphabetical sections, financial particulars of British limited liability companies, also of foreign companies with a British address.



A new feature, which has been asked for, is the separation of the London from the provincial names in the British alphabetical section.

The lists of electricity undertakings in the United Kingdom, British colonies and some other countries include the following details: The nature of the supply, system of distribution, capacity of plant, voltage and chief engineer's name, and in the case of alternating current, the phase and periodicity are included.

A list of specialties appears in the British Section, arranged alphabetically, according to the name of the article, followed by the maker's or agent's name and address. This, judging by enquiries, should supply a present-day want.

"PRACTICAL ENGINEER" POCKET BOOK—Issued by the Technical Publishing Co., 55 and 56 Chancery Lane, London, W.C., England; 800 pages. Price, 40 cents postpaid.

In this new 1911 issue obsolete data has been dropped and several new topics treated. The new matter includes notes on stoker systems, thermal storage, superheaters, roller bearings, etc. Revision has been made of articles dealing with shop gauges, patterns, etc. Over 700 pages are devoted to subjects of interest to the engineer and mechanic, the remaining pages being blank and arranged for diary and notes.

BROWNING

How many mill owners have warded off the thought of buying a Locomotive Crane for handling of their logs and dimension timbers, thinking the equipment a LUXURY? Later you would be surprised at the great number of these same mill owners who, after seeing their smaller competitor install a "BROWNING," have investigated and found the outfit a NECESSITY and a money-saver instead.

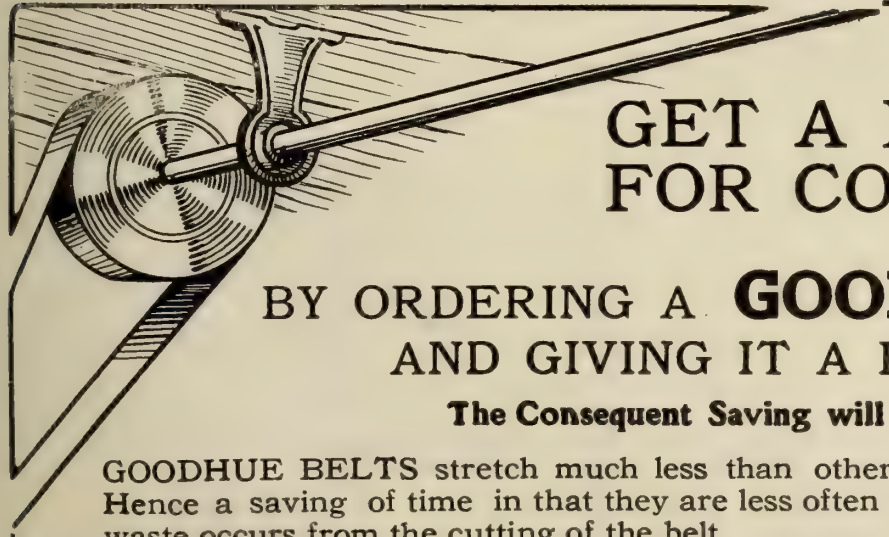
About Wear and Tear on New Process Noiseless Pinions

Just observe from this picture how well a New Process Pinion wears in hard service. This pinion has driven in both directions and still transmitted full load after the teeth had worn down to a knife edge. No guessing about the quantity and quality of work done here, is there?



Of course, the teeth of a New Process Pinion wear out in time as do those of a metal gear, but **they do not break or strip or tear out.** You can depend upon them for the same good, honest service as from any metal gear, but without the noise. ***Ask for Booklet.***

Economical, Efficient, Satisfactory

A very efficient tool which should find a place in every machine shop is

BLOUNT'S WET TOOL GRINDER

which can be run continuously if desired.

It is fitted with self-oiling bearings, and there is no wearing of parts, because the propeller of the pump, furnishing a constant supply of water, is loosely fitted, and does not touch the case at the nearest point. A sleeve cap prevents leakage without the use of packing.

Satisfaction Guaranteed.

BRITISH and Continental Buying and Sales Agency, Metals, Hardware, Chemicals, Paints, etc. Englishman (established in Birmingham) with wide merchant and export experience in above and allied trades, is open to negotiate with first-class firm to act as Buying or Selling Agent. Advertiser is thoroughly acquainted with best British and Continental sources of supply and possesses valuable home and foreign connections. Bankers and commercial references Apply "Business," care John Lewis & Co., Chartered Accountants, Birmingham. (1)

POSITIONS WANTED.

FOUNDRY FOREMAN open for engagement or as assistant in large shop. Machinery line. Best of references. Box 110, CANADIAN MACHINERY, Toronto.

PAINTER AND LETTERER, 35, wants position as foreman or under. American and Canadian experience with car, locomotive machinery, bridges, etc. Construction firms in States or Canada. Good bonus given for procuring same. At liberty in a month. Write Box 56, CANADIAN MACHINERY, 88 Fleet Street, London, England. (3)

LIVE MAN, thoroughly practical and theoretical. Experienced improving machine shop methods and efficiency. Piece work; time study; demonstrating. Tactful and diplomatic in handling men. Excellent references. Box 108, CANADIAN MACHINERY, Toronto. (2)

MISCELLANEOUS.

A BOOK-KEEPING STAFF IN ITSELF—doing the work with machine-precision and accuracy, the National Cash Register. Write us for demonstration literature. National Cash Register Co., 285 Yonge St., Toronto.

ACCURATE COST KEEPING IS EASY if you have a Dey Cost Keeper. It automatically records actual time spent on each operation down to the decimal fraction of an hour. Several operations of jobs can be recorded on one card. For small firms we recommend this as an excellent combination—employees' time register and cost keeper. Whether you employ a few or hundreds of hands, we can supply you with a machine suited to your requirements. Write for catalog. International Time Recording Company of Canada, Ltd. Office and factory, 29 Alice Street, Toronto.

COPELAND-CHATTERSON SYSTEMS — Short, simple. Adapted to all classes of business. Copeland-Chatterson-Crain, Ltd., Toronto and Ottawa. (tf)

COUNTER CHECK BOOKS — Write us to-day for samples. We are manufacturers of the famous SURETY NON-SMUT duplicating and triplicating Counter Check Books, and Single Carbon Pads in all varieties. Dominion Register Co., Ltd., Toronto.

DOUBLE YOUR FLOOR SPACE. An Otis-Fensom hand-power elevator will double your floor space, enable you to use that upper floor either as stock room or as extra selling space, at the same time increasing space on your ground floor. Costs only $70. Write for catalogue "B." The Otis-Fensom Elevator Co., Traders Bank Building, Toronto. (tf)

ELLIOTT-FISHER STANDARD WRITING-ADDING MACHINES make toil easier. Elliot, Fisher, Limited, Room 314, Stair Building-Toronto.

EGRY business systems are devised to suit every department of every business. They are labor and time savers. Produce results up to the requirements of merchants and manufacturers. Inquire from our nearest office. Egry Register Co., Dayton, Ohio; 123 Bay St., Toronto; 258½ Portage Ave., Winnipeg; 308 Richards St., Vancouver.

FIRE INSURANCE. Insure in the HARTFORD. Agencies everywhere in Canada. (tf)

INDISPENSABLE in office, store, home—Canadian Almanac, 1911—a National Directory. Complete classified information on every subject of Dominion interest. Full Postage, Customs, Banking, Insurance, Legal, Educational, Newspaper, Army, Clerical, Governmental, Particulars of leading Institutions and Societies. Paper Covers, 60c. Cloth, Leather Back, 75c. All stationers, or sent postpaid on receipt of price by The Copp-Clark Co., Ltd., Toronto.

MACHINERY

SALESMAN WANTED for machine tools and supplies (specialties) with good practical experience and good trade connections, especially in Ontario; must be order getter and able to work up business. Give full particulars, past experience, salary, etc. Confidential. Apply by letter to SCHUCHARDT & SCHUTTE, 90 West Street, New York. (4)

MISCELLANEOUS.

KAY'S FURNITURE CATALOGUE No. 306 contains 160 pages of fine half-tone engravings of newest designs in Carpets, Rugs, Furniture, Draperies, Wall Papers and Pottery with Cash prices. Write for a copy—it's free. John Kay Company, Ltd., 36 King St. West, Toronto.

MODERN FIREPROOF CONSTRUCTION—Our system of reinforced concrete work, as successfully used in many of Canada's largest buildings, gives better results at lower cost. "A strong statement," you will say. Write us and let us prove our claims. That's fair. Leach Concrete Co., Ltd., 100 King St West, Toronto. (tf)

MR. BUSINESS MAN, are you progressive? It's up to you to test "Consolidated," our new process carbon paper. Because it costs less. Soft finish, without smutting, and clear, permanent copies. Write for sample sheets and prices. "Consolidated," Stratford, Ont.

MAKE MONEY AND SAVE MONEY with the Multigraph. It does multiple typewriting and real printing, 1200 to 5000 sheets an hour; gets new business with form letters or printed advertising; saves 25% to 75% of printer's charges on stationery and forms. American Multigraph Sales Co. Ltd., 129 Bay Street, Toronto.

MOORE'S NON-LEAKABLE FOUNTAIN PENS. If you have Fountain Pen troubles of your own, the best remedy is to go to your stationer and purchase from him a Moore's Non-Leakable Fountain Pen. This is the one pen that gives universal satisfaction and it costs no more than you pay for one not as good. Price $2.50 and upwards. W. J. Gage & Co., Limited, Toronto, Sole Agents for Canada.

RETAIL MERCHANTS and others with a limited correspondence will find it to their advantage to write us for catalogue of special bargains in rebuilt typewriters. We have all the well-known makes, taken as part payment on the MONARCH, and at the prices we offer them, they are remarkable bargains. THE MONARCH TYPEWRITER CO., Ltd., 46 Adelaide St. West, Toronto, Ont.

"SYSTEMS" stand for all that is best in loose-leaf binders and supplies, letter-heads, statements and in fact your office stationery of every description. Send us samples of what you are using—we will send you prices that will interest you. Business Systems, Limited, Manufacturing Stationers, Toronto. (tf)

THE "Kalamazoo" Loose Leaf Binder is the only binder that will hold just as many sheets as you actually require and no more. The back is flexible, writing surface flat, alignment perfect. No exposed metal parts or complicated mechanism. Write for booklet. Warwick Bros. & Rutter, Ltd., King and Spadina, Toronto.

WAREHOUSE and Factory Heating Systems. Taylor-Forbes Company, Limited. Supplied by the trade throughout Canada. (tf)

BELTING, PACKING, ETC.

BELTING, RUBBER, CANVAS AND LEATHER, Hose Packing, Blacksmith's and Mill Supplies at lowest price. N. Smith, 138 York Street, Toronto. (2tf)

RUBBER STAMPS, ETC.

B. CAIRNS, MANUFACTURER OF RUBBER stamps, stencils, steel stamps, burning brands. 77-79 Queen Street East, Toronto, Ont. (tf)

MANUFACTURING CENTRES.

FREE FACTORY SITES—Seven railroads, deep water, Niagara power, natural gas, low taxation, abundant labor. Welland, Ontario. B. J. McCormick. (12y)

LUMEN BEARING COMPANY, TORONTO

High Grade Malleable Castings

of all sizes and kinds

Galt Malleable Iron Co., Limited - Galt, Ontario

We build nine sizes of Stokers, capacity from 25 to 2000 lbs. coal per hour.

Write Now!

Our Furnaces Heat Steel with the Cheapest Fuel on Earth—

SOFT, SLACK COAL

They are all fired with "American" Mechanical Stokers, which burn bituminous slack coal automatically and without smoke, and give a clear, steady, soft, non-scaling flame. You get increased production, at about one-third to one-half the operating cost of oil or hard coal. This is a fact. If you burn money to heat steel why not burn less of it, and write us at once?

The Standard Engineering Company Limited

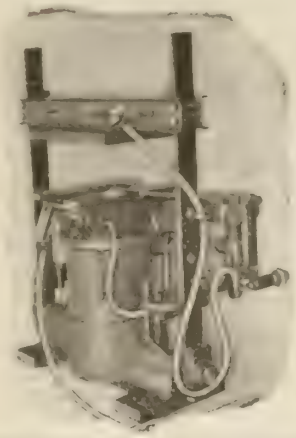
MARINE ENGINES and PUMPS. SHOE MACHINERY A Specialty

BRASS and IRON CASTINGS. BOILERS and REPAIRS.

That we have exceptional facilities at our disposal for the manufacture of all kinds of Machinery—in addition to our business as Brass and Iron Founders, General Contractors and Shoe Machinery Engineers—has been amply proved this year. In the short space of five months, we built and installed all the Engines and Boilers of the new sister steamers "Levis" and "Lauzon," whose trial trips were a complete success. We make a specialty of all kinds of Marine Engine Work, and shall be glad to quote for first-rate products only.



SHOE MACHINERY. Manufacturers of "Non-Royalty" Machines, Metallic and Goodyear, "Fortuna" Skivers, and "Climax" Presses, Sand-papering, Lasting and Loose Studding Machines.

The Making of Hollow Castings

The recent introduction of King Kore Kompound has now rendered this, once somewhat difficult, part of Foundry practice comparatively easy.

It has, also, reduced the core expense by more than one-half.

This compound is a black, dry powder, and is used as flour is used, but with one-half the quantity is produced greater and better results.

Its use avoids the danger of swelling or "blowing." The core easily comes out of the casting, and when old cores are ground up, in the rattler, or otherwise, the sand so made is used over again.

The core compound it contains, again becomes a binder under heat of the core oven, as it melts, and so it is used over and over again.

This is Foundry Economy; Flour, Rosin, etc., are now luxuries.

A barrel of King Kore Kompound will be sent "subject to approval" to any inquiring mind.

That is the **Stevens' System** of trying before buying.

I have copies of proportions of compound to sand used and methods followed in core rooms of Foundries in thirteen different States. This information, with other printed matter relative to the subject, will be mailed on request.

I maintain a direct branch at 137 Jarvis St., Mr. J. M. Mayers, Manager, Toronto, Ont., where is stocked a supply of **Foundry Facings, Foundry Supplies, Buffing Compositions**, of my own manufacture.

The stamp of quality pervades them all.

A GOLD MINE

SAVE YOUR IRON

SLY'S PATENT IRON CINDER MILL
Patented, No. 514097. Patented, No. 841728.

may be at your disposal on your very premises. Look out of your side window or back door and see if you have not an accumulation of cupola dump, and other foundry refuse, which is a total loss to you in its present state. Why not add to your profits and install one of the Sly Patent Cinder Mills to reclaim this iron and be astonished at your former loss and pocket the rich returns from your newly-discovered mine.

Sly's Patent Iron Cinder Mill will save 95% of the iron contained in your cupola dump and gangway scrapings and 75% of the coke. Iron is valuable, then why throw it in the dump? Iron recovered by this Mill is better than machinery scrap. Study economy in a foundry and your profits will increase accordingly. Mill will pay for itself three or four times every year, and we have records of Mill paving for itself twelve times a year. Let us know amount of your daily melt and we will quote. *Write for Cinder Mill Catalogue F.*

We also manufacture Cleaning Mills, Dust Arresters, Sand Blast and Foundry Equipment.

The
Foundry and Machine Exhibition Company
Will hold their
1911 EXHIBITION

Of Foundry and Machine Shop Tools and Equipment, Pattern Shop Machinery, and all lines of supplies and appliances used in manufacturing industries in the city of

Pittsburg, May 23rd to June 1st

The large buildings of the Western Pennsylvania Exposition Society, located on Duquesne Way, in the centre of the Pittsburg business district, have been secured for housing these exhibits. The two main buildings have a floor area of 65,000 square feet, and more than 40,000 square feet will be available for exhibit purposes.

The Annual Conventions of the American Foundrymen's Association, the American Brass Foundrymen's Association, and the American Foundry Foremen's Association, will be held during the first five days of the exhibit, and the Annual Summer Meeting of the American Society of Mechanical Engineers will be held in the city of Pittsburg during the last three days of the exhibit. The meetings of these organizations and the exhibition will attract large numbers of men interested in the manufacturing industries, and an unexcelled opportunity is offered to study the exhibits of Foundry and Machine Shop Equipment.

FOUNDRY ECONOMY

is attained by the use of high-grade

The Strongest Drive for Large Size 'Flatwist' Drills

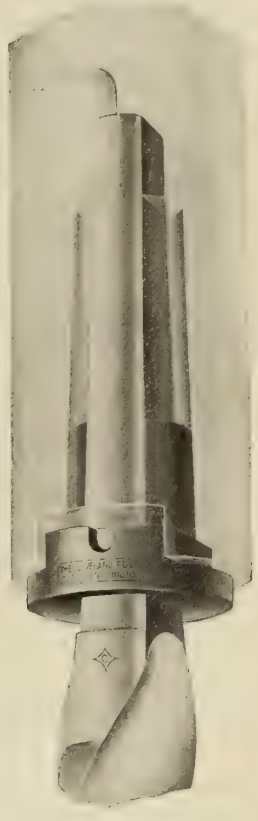
"Paragon" Collet No. 800-A

is practically an interchangeable taper shank for "Flatwist" drills. The drive is on the HIGH SPEED STEEL TANG.

"Paragon" Collet No 800-B

provides a powerful additional drive at the lower and stronger end of the shank by means of a projection which mortises into the spindle.

YOUR heavy duty drilling can be accomplished with precision by using the powerful compact drive provided by these



"PARAGON" COLLETS

Pat. Nov. 22, 1910

THEY allow drilling at higher speeds with absolutely no twisted-off tangs. "Paragon" Collets eliminate cumbersome extension reducing sockets by simply adapting the Nos. 5 and 6 "Paragon" shanks directly to the drill press spindles.

"Paragon" Drills are forged hot from flat bars of the best high-speed steel, without weld or joint. The combination of the "Paragon" Drill and Collet means ***efficiency.***

May we send our Folder No. 31C giving the facts and prices?

"Paragon" Collet No. 800-B

showing its engagement with the lower end of the spindle—the strongest known drive for "FLATWIST" DRILLS.

ACCURACY

To make Twist Drills that will do absolutely accurate work requires the greatest skill—years of experience and the most careful attention to each detail of manufacture.

To secure the greatest wearing quality requires the best of steel, tempered to exactly the correct degree of hardness. Not all Twist Drills attain these two essentials, but

"W & B-DIAMOND"

Twist Drills do and we ***guarantee*** them to be of ***highest quality*** and ***accurate to size.***

We make them from Carbon Steel and Vanadium High Speed Steel and carry the largest stock in Canada.

The "Hercules" High Speed Twist Drill shown on this page is one of our many types and is ***twisted*** while hot from Vanadium High Speed Steel.

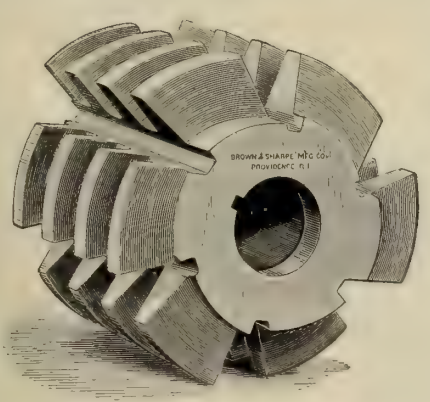
Judge Us By Our Records!

WHEN we first started in the DRILL CHUCK business we only manufactured our No. 2 Chuck, but almost immediately we received orders for other sizes which we have added from time to time as conditions would permit, until now we manufacture ten different sizes and forms of the JACOBS IMPROVED DRILL CHUCK, all of which are in constant demand. Although we have not employed a salesman in the past three years, our sales have constantly increased, and the year just passed has been the most prosperous year in our history.

The Jacobs Manufacturing Company
Hartford, Conn.

FIRE BRICK *for* Cupolas

¶ The standard Fire Clays by which all other Clays are judged are those of Pennsylvania.



¶ They're the ones from which our Cupola Brick are made.

¶ The cost per thousand means nothing unless you know the results the Brick are giving.

¶ Write us for definite examples of how our material affects your melting costs.

HARBISON-WALKER REFRACTORIES COMPANY,
PITTSBURGH, PENNSYLVANIA

Do You Cut Worm Wheels?

If so, accurate hobs are a necessity. The slightest error in a hob is apparent in the finished work. A worm and wheel inaccurately cut will not mesh correctly, producing unnecessary friction and subsequent loss of power.

We Make Accurate Hobs of Any Size.

Specially designed machines make it possible for us to cut hobs of any size. They cut as freely as formed cutters and, like formed cutters, can be sharpened by grinding the tooth faces. Worm wheels cut with these hobs are mechanically correct.

Write us, giving your requirements. We can meet them.

Brown & Sharpe Mfg. Co.

Providence, R.I., U.S.A.

CANADIAN FOUNDRYMAN BUYERS' DIRECTORY

To Our Readers—Use this directory when seeking to buy any foundry or pattern-shop equipment. You will often get information that will save you money.

To Our Advertisers—Send in your name for insertion under the heading of the lines you make or sell.

To Non-Advertisers—A nominal rate of $1 per line a year is charged non-advertisers.

This New Gap Lathe Will Work Better—Faster Than Any Other

THE two main features of this New Gap Lathe are Rigidity and Speed of Adjustment and Operation. Notice the extra strong construction of the Gap The most severe strain will not cause the carriage or apron to spring. It is impossible for the headstock to chatter. The tailstock is adjusted from the top by set-screws, saving much of the operator's time. Friction safety feeds give quick changes of thread, and eighteen distinct spindle speeds are given by double back gears. You will find that this new lathe will do its work faster and better than any other. Full equipment with each lathe.

Headstock construction prevents chattering, and deep oil chambers fitted with ring oilers make spindles and bearings self-oiling and always well lubricated.

Tailstock of a special type, and sleeve is clamped by a quick acting locking device. Tailstock is secured to bed by bolts adjusted from the top where they are easily accessible.

Bed, non-springing and webbed, and braced to secure rigidity.

Gap, vibration absolutely prevented by use of brace supports to carriage.

Spindle, high carbon hammered steel in solid chilled cast iron bearings, accurately fitted and self oiling.

Carriage and Apron, non-springing under severest strain, full "V" bearings and flat bearings in addition on front ways.

Double Back Gears give eighteen distinct spindle speeds, suiting lathe to work on widely different diameters.

Compound Rest, with graduated base, accurately fitted taper gibs, end adjusted. Screws in both rest and cross slide read to thousandths.

Friction, Safety Feeds, screw and rod feeds cannot be both engaged at the same time. Quick changes of 1¼, 2½ and 5 times thread being cut.

Gears and Racks, cut from solid and steel where necessary.

Screw Cutting, full range of commercial threads provided for

Equipment, Compound rest, steady rest, follow rest, large and small face plates, wrenches, two-speed, friction countershaft furnished with each lathe.

Accuracy, Strength, Solidity, Wear. These are the paramount features behind all McDougall Machines. Made to meet extreme demands.

Bertram Boring and Drilling Machines

72-Inch Bertram Horizontal Boring and Drilling Machine---Motor Driven

These machines are designed for work on irregular pieces which are difficult to hold, as a number of parallel holes may be drilled and bored at one setting.

We manufacture several sizes of **Horizontal Boring and Drilling Machines,** all of which are readily convertible from belt to motor drive.

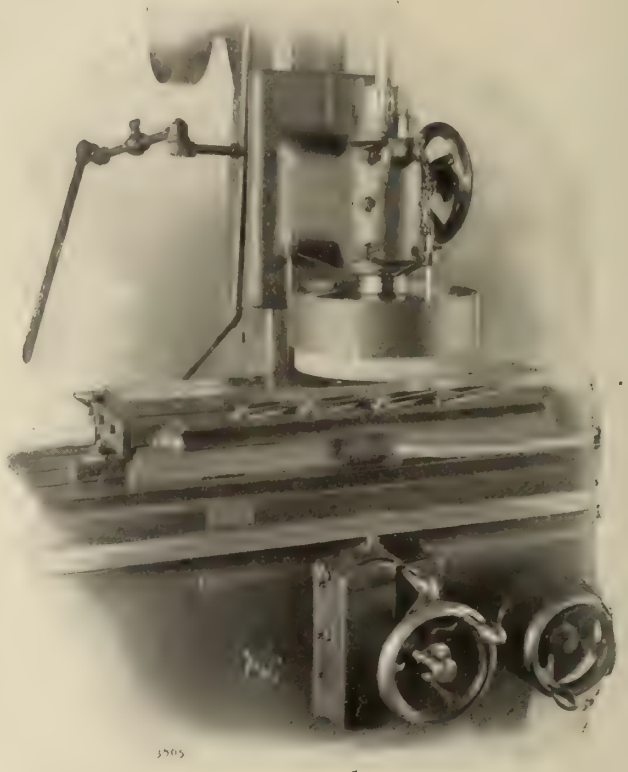
A Revolution in Surface Reduction

The P. & W. Vertical SURFACE GRINDER

The New Method of Surface Reduction that is Rapidly Displacing Milling and Shaping Operations

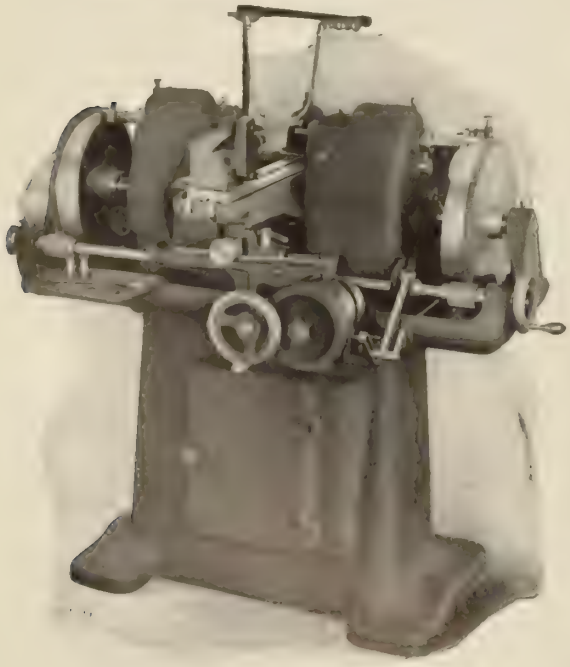
10 to 25 times faster than milling.

Produces an absolutely flat surface with a mirror finish and grinds uniformly to within 0.0002 inch.



Works directly on the rough and hardened forging or casting.

Overcomes all surface errors that were impossible to correct in milling, shaping or vertical wheel grinding operations.



Working surface 10¾ x 36 inches.

"Grinding, not Milling," is the new shop slogan.

Write for book "Grinding, not Milling."
It illustrates over 75 economical applications in all branches of machine manufacture.

Partial View of the P. & W. Vertical Surface Grinder, showing cup-shaped grinding wheel and magnetic table.

P. & W. Spline Milling Machine

No More Trouble or Expense to Mill a Slot with a P. & W. Spline Milling Machine

Than to drill a hole with a drill press.
Cutters used are cheaper than drills.

To obtain a tang slot or key-way, a cutter, the diameter of which represents the width of slot desired, is placed in collet, table traverse set for length, and, in case of a key-way, the cams set to limit the depth, and the power thrown in.

Operation is entirely automatic.

No starting-hole, lay-out, hand-milling or vise-work required.

Write for Catalog "Spline Millers."

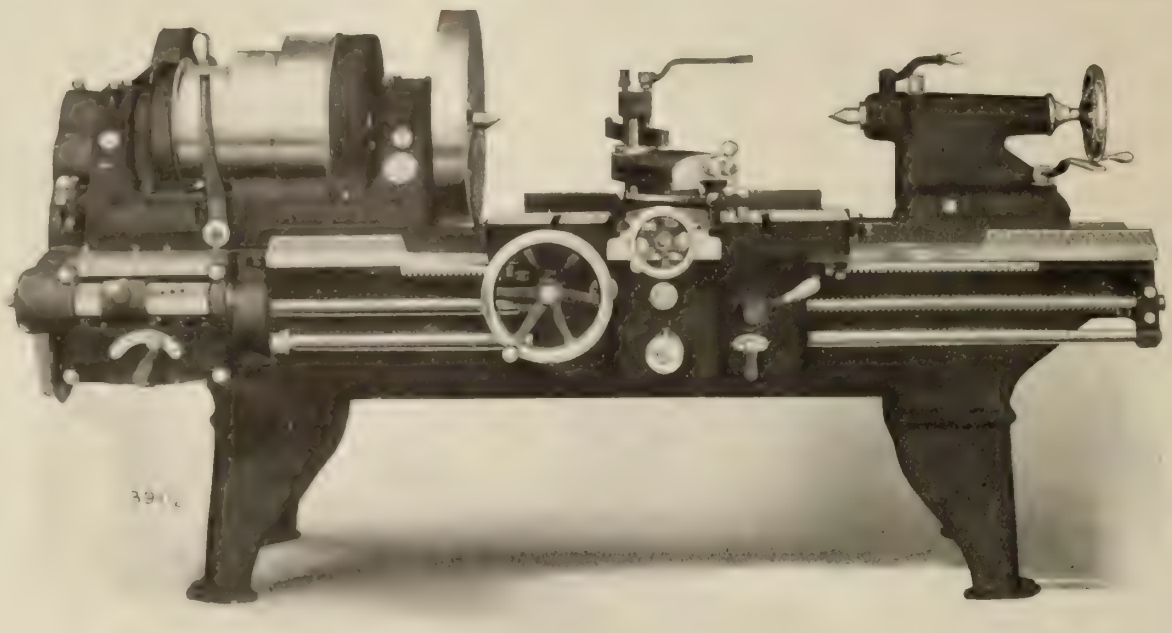
Westinghouse Motors for Pumps

A satisfactory pump is the kind you can start, and not bother with again until ready to stop it.



Westinghouse 125 H.P. Motor Driving 4½ x 12½ Quinterplex Pump, 200 Gallons Capacity, 750 pounds pressure.

Westinghouse motor-driven pumps are that kind; the motor will operate efficiently and continuously for days or months. They practically take care of themselves. For intermittent service the motor may be automatically started and stopped by means of a pressure regulator or by variation in the height of water. Our nearest office will give you full information.

Canadian Westinghouse Co., Ltd., Hamilton, Ont.

TORONTO	MONTREAL	HALIFAX	WINNIPEG	CALGARY	VANCOUVER
Traders Bank Building	52 Victoria Square	Telephone Bldg.	158 Portage Avenue East	311 8th Avenue West	439 Pender Street

Cost Reducing Features

An indestructible spindle bearing made of hardened steel and cast iron.

A head construction that gives more effective pulling power at the spindle than any other lathe built.

A patent "Compensating V" that permits four times the bearing area between the carriage and bed found on other lathes.

A carriage in which the tool thrust is taken on a bearing the entire length of the carriage, and which positively will not climb the V.

A double-walled one-piece apron which will last as long as the rest of the lathe.

A quick change gear complete in one unit, giving thirty-six changes with two operating levers.

An offset compound rest which can be used without skinning the operator's knuckles.

The centres set back of the middle of the bed, giving greater swing over carriage and permitting the turning of work up to the maximum swing without the tool overhanging the bed.

Becker Vertical Spindle Milling Machines

New Model "C" for Heavy Milling

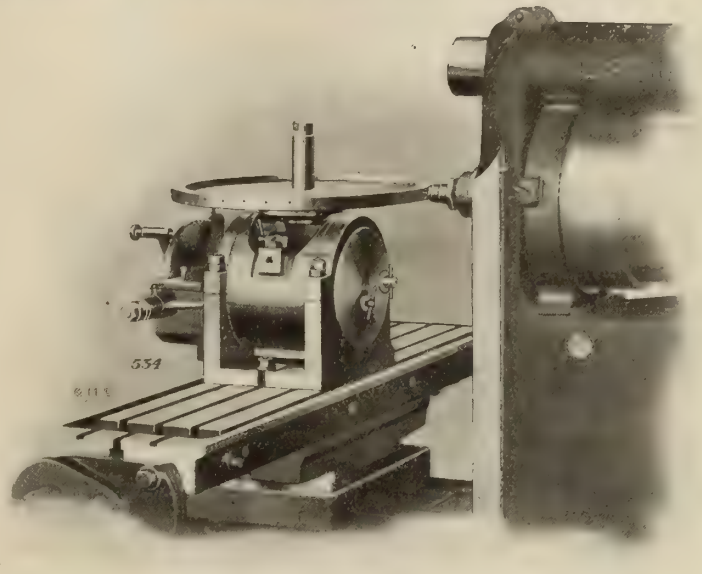
Some Features of this Machine

THE QUESTION OF POWER CONSUMPTION is one needing special consideration. It is generally considered that all-gear driven spindles consume much more power than an open belt driven machine. Model "C" Vertical can be driven by a 5h.p. variable speed motor. Tests made show a consumption of 4 electrical h.p. when removing 20 cubic inches of cast iron per minute, and when milling soft steel at the rate of 10 cubic inches per minute a 5h.p. consumption. We solicit a comparison of this test with results made by all-gear driven vertical milling machines.

THE ADVANTAGES OF OPERATING A MILLING MACHINE SUCCESSFULLY on heavy cuts without back gears in mesh is too well known to need enlarging upon. We desire only to call special attention to the fact that the Model "C" is designed to perform satisfactorily the average work in the average shop without any spindle gears in mesh. Constant torque of the spindle under direct belt action insures smooth work and reduces chattering, thus making the new Becker a power in its field.

Full specifications on request. Catalogue 56C for general description.

THE BECKER MILLING MACHINE COMPANY, HYDE PARK, MASS., U.S.A.



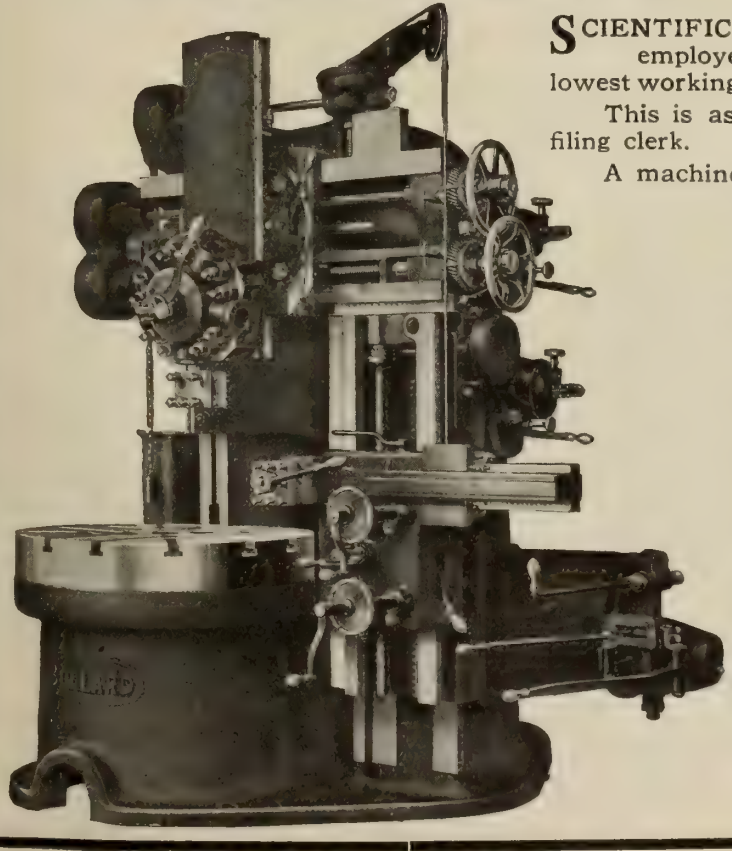
The advertiser would like to know where you saw his advertisement—tell him.

CINCINNATI UNIVERSAL TOOL ROOM MILLERS

Thirty-six holes ¼ inch diameter are spaced on the periphery of a 19 inch disk rigidly held on a 12 inch Index Head. They are first drilled, then bored a trifle under size, and finally reamed to a plug gauge fit with a specially ground ¼ inch end mill. The error between holes is less than one thousandth (—.001 inch). To get such results requires a miller that is accurate all over.

This is a good illustration of the best method of handling work of larger diameter than the index centres will swing. The swivel trunnions on our Dividing Head are large in diameter and fully protected in all positions, insuring permanency of alignment at any angle to which the spindle may be set.

Cincinnati Millers are as famous for their accuracy as for their productive capacity.



The Cincinnati Milling Machine Company

CINCINNATI, OHIO, U.S.A.

Canadian Agent—H. W. PETRIE, Limited, Toronto, Montreal and Vancouver.

Working as Rapidly at 3 p.m. as at 9 a.m.

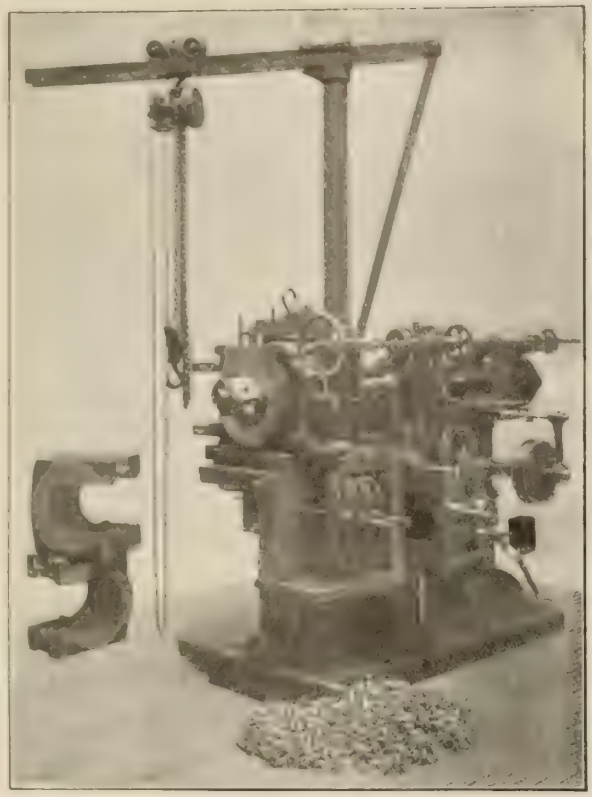
SCIENTIFIC Business Management has proved that an employee working from morning until night strikes his lowest working vitality about 3 p.m.

This is as true of the machine tool operator as to the filing clerk.

A machine that is hard to operate—that requires severe, laborious exertion — that requires constant movement to an fro—begins to waste its operator's strength in the morning and leaves him exhausted at the end of the day.

Production suffers — ***quality of work*** suffers.

In the Bullard Vertical Turret Lathe the strain is taken off the operator by ***Power Rapid Traverse.*** Also all levers and handles are directly before him within his reach.



Power Rapid Traverse sets a rapid pace for the operator which he almost unconsciously follows. And by conserving his strength it enables him to work at this rapid pace ***all day.*** Production at 3 p.m. is as ***rapid*** and ***quality*** of work as accurate as at 9 a.m. This means a direct and ***very appreciable*** saving on cost of production of all face plate work within the Vertical Turret Lathe's range.

Ask for Treatise on Face Plate Work, C-15.

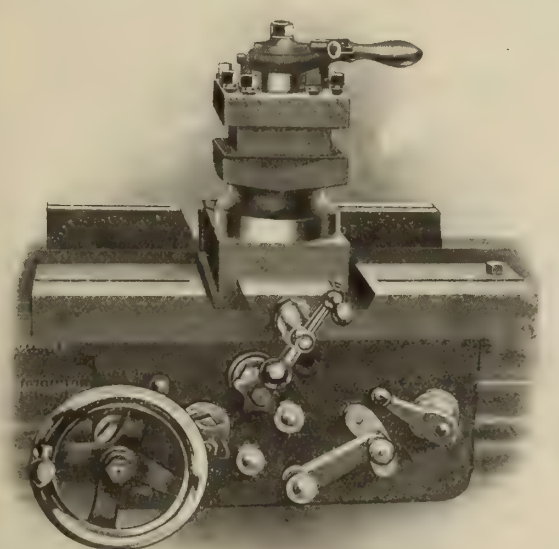
Here is the Machine That will Meet *Your* Requirements.



It is constructed on practical lines and does the finest kind of work. This disc and surface grinder is especially adapted for pattern shops die makers and all kinds of tool and surface grinding.

Disc side has table tilting from 0 to 43 degrees. Size of disc table, 10 x 10 in. Diameter of disc, 18 in.

It will solve your vibration problem. It is strongly built of one solid casting; and satisfactory tests have demonstrated that vibration is avoided.

Our Catalogue will Interest You. Write for it now.

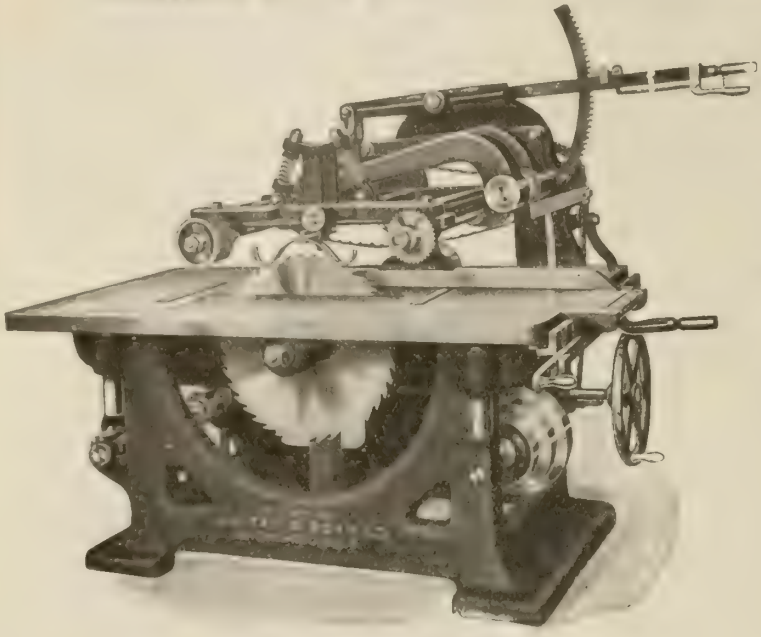
The Feed Mechanism of the Sibley Hi-Speed



THE Feed Mechanism derives its power from the main drive shaft which directly rotates the spindle and is geared down in such generous ratios that an unusually powerful feed is obtained. The gear case is very compact and the gears are always in mesh. These, together with the steel worm, run in an oil bath. Four changes and a neutral position are made by moving a knob in the centre of the hand wheel. A positive adjustable collar on the graduated spindle sleeve trips a latch at the desired depth and the entire mechanism swings away from the worm gear on a large hinge pin. A special wear-resisting bronze alloy is used in the worm gear.

Sibley Machine Tool Company
Church Lane
South Bend, Ind., U.S.A.

OUR
No. 264 SELF-FEED RIP SAW

Embodies in its construction all features that are necessary for the satisfactory handling of light or heavy material.

No. 264 Self-Feed Rip Saw.

It is equally efficient in ripping SHORT or LONG Stock. Both the in-feeding and out-feeding roll may be adjusted close to the saw, permitting short stock to be fed without trouble.

The Feed Rolls may be instantly raised, converting it into a hand-feed machine when desired.

The table raises and lowers to accommodate different thicknesses of stock.

Capacity—Rips 4 in. thick with a 16 in. saw, and 8 in. with a 24in. blade. Takes 19in. between saw and fence.

A High-Grade Small Engine Lathe at Moderate Cost!

With or Without Quick Change Gear Device.—Three or Five Step Cone. You can use one in YOUR shop.

FREE from fussy attachments and mere talking points, the Von Wyck 15-inch engine lathe offers such a combination of convenience and economy that operators maintain, "It is unequalled by any lathe of its swing."

WHY buy a large size and pay a big price to get great strength and efficiency? Von Wyck design and construction are thoroughly high grade in every important detail and satisfactorily cover an unusual range of work.

The Cost Per Piece On Your Small Parts

SHOULD BE THE LOWEST

This is the problem which we have been working on for years, and we have solved it. Wherever you find **Acme Automatic Multiple Spindle Screw Machines** you will find low costs, and the method is responsible.

There are four spindles carrying stock upon which as many as eight tools work at the same time. The Drive is Single Belt or Motor; the Control is One Lever; there are no reversals. The time for completing any piece is that required to perform the longest cut.

If you are not in a position to make the parts, send us your samples for quotations, or get our Catalogue on Standard Screws and Nuts. We guarantee quality, and the price is consistent with low costs.

The advertiser would like to know where you saw his advertisement—tell him.

"Even Exchange is no Robbery."

If you will send us your name and address, writing us on your business stationery, making positive statements as follows:—

First—That you are in the machine business for yourself;

Second—That you use in your shop, or factory, as many as four Drill Chucks;

Third—That you do not use the Jacobs Improved Drill Chuck;

Fourth—That you saw this offer in the May issue of Canadian Machinery;

we will, upon receipt of such information, send to your address, without cost to yourself, one of our No. 2 Drill Chucks, having 21/64 inch capacity. This offer is good only until June 1, 1911.

This is not a "Gold Brick" Offer

It means dollars and cents to you. We have sold more than 100,000 Jacobs Improved Drill Chucks. Of these, more than 48,000 were the same as the Chucks which we are offering you, and we never sold one of these Chucks to a consumer for less than $3.85.

Why do we make this offer? Because we know that when you learn the true value of the Jacobs Improved Drill Chuck, you will become one of our satisfied customers. A satisfied customer is of more value to us than a Drill Chuck, and as a Drill Chuck will be of more value to you than the letter you write, the transaction will be mutually profitable.

Our new thirty-four page illustrated catalogue, showing half-tone illustrations, actual size, of the ten different sizes and forms of the Jacobs Improved Drill Chuck, will be sent to you free upon request.

ABSOLUTELY FREE--The Sheet Metal Workers' Handbook

A NEW BOOK JUST OUT.

It tells how to fasten two pieces of Sheet Metal together without Soldering or Riveting.

No Holes to Punch. No Rivets to Set.

It tells about the "Electric Way" of spot welding: how it's made and why it's cheaper than riveting. Shows convincing proof that a spot weld is 60% stronger than a rivet—looks neater and is absolutely safe for the operator.

QUICK? Say---it's so quick that greased lightning is a canal boat for speed by the side of it.

This shows only one kind of machine illustrated in this book and some of the work done on it. It's a hand operated—stationary lever machine. They are made with swivelled lever handles—or can be furnished to be power driven or foot operated with depth of throat 14 in., 24 in., 30 in., 36 in., or 48 in., but the book tells all about this and more. It also gives a hint on butt welding machines. It's yours for the asking.

No Lease. No License. No Royalty.

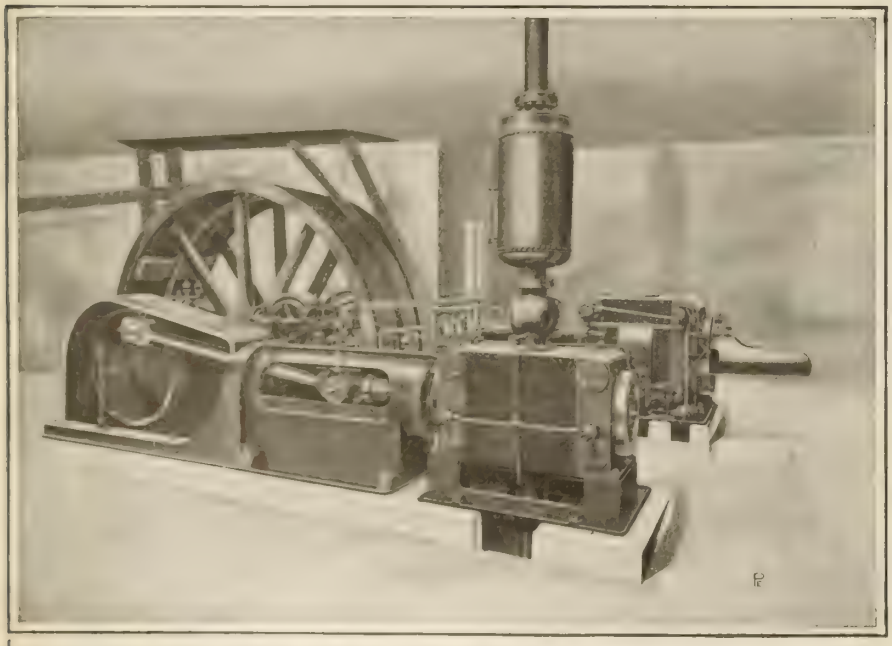
McEWEN
High-Speed Automatic
ENGINES

Are built essentially for the economical production of electric light and power. Directly connected to dynamo, they cannot be equalled for smoothness of running, absolute reliability, and for the capacity to absorb overload without flinching. They are built in simple and compound units up to 700 H.P.

The McEwen Engine Catalogue will be sent on request.



The Waterous Engine Works Co.
Brantford - Canada

Specifications

All parts are few and simple and are built to template, so that repairs can be quickly furnished. The bed is heavy and rigid, combining great strength with accessibility for all adjustments. Crosshead guides, main bearings, and face for cylinder attachment are machined in one operation. Connecting rod, of marine type, is slotted from the solid forging. Cylinder casting, of the best close-grained iron, is deep enough to permit reboring, and has front head cast solid. The flat side valve, double ported and frictionless, is held in place by a balancing pressure plate, slotted to correspond with the valve seat. This produces additional passage to the cylinder by providing double admission and exhaust edges. Relief valves are absolutely unnecessary. Crosshead shoes have a special eccentric bolt adjustment, which is simple, rapid, and perfectly accurate. The special feature of these engines is the guaranteed control by the Begthrup Governor. This, the first successful shaft governor built, permits instantaneous regulation without flinch when changing from full load to no load.

Guarantee

The engine shall not run one revolution slower when fully loaded than when running empty, and a reduction of boiler pressure from the greatest to that necessary to do the work, will not reduce the speed of the engine one revolution. Any engine failing to meet this guarantee becomes the property of the purchaser upon the payment of one dollar.

Cross Compound Goldie Corliss at Cosmos Cotton Co., Yarmouth, N.S. Rope Drive.

Reliability is the most important consideration in the selection of a Power Plant.

Manufacturers above everything else must have a steady day in and day out service.

SHELDONS LIMITED - GALT, ONTARIO

REMOVING THE APPENDIX

Would you have this operation performed by some doctor who offered to do it cheap or by an experienced successful specialist? We know the answer.

The same principle applies in many other directions. There has been a wonderful change in the intellectual broadening of operative Engineers and Mechanics. They are no longer satisfied with merely keeping the machinery in good running order. They start in at the coal pile and study the califoric power of fuels in thermal units, the firemen are put through a school of instructions, and they study economies and scientific problems in many other directions,

BUT How many Engineers and Mechanics figure on the loss from frictional resistance in transferring the power from the boiler to the points where it is needed?

More than half of the power is often absorbed in that way and yet many up-to-date men use or permit to be used the most ordinary grades of babbitts because of the slight initial saving in the cost price.

It Is Plain as an Open Book

that the value of a genuinely good and economical bearing metal is summed up in and expressed by a low co-efficient of friction.

A low co-efficient of friction means less frictional resistance, less wear, less heating, less oil, less fuel, less liability of shut downs, less rebabbitting, less consumption of metal, less squashing, less worry, less work. You can secure all of these economies and other advantages by the use of

Magnolia Metal

and we recommend its uses on shafting as well as all other bearings. We represent the specialist who does one thing and does it well.

Special Offer

PRACTICAL ENGINEER POCKET BOOK, 680 pages, over 2,000 subjects. We do not aim to make a profit on this book and therefore offer it at the very low price of 40c., postpaid Many Engineers write to us that they find it invaluable. Address Montreal office.

"GET ME A SILENT PARTNER"

THAT'S what every ringing, rattling, roaring gear would say if it could talk in words. Noise in gear drives is only evidence of undue friction and wear, loss of power and ruin of parts.

There's no better or surer relief from noisy, vibrating gear drives than the substitution of **New Process Noiseless Pinions** for the metal pinions. A New Process Noiseless Pinion, like any other good silent partner, works well with its mate, and there is minimum of friction.

Motor drives with New Process Noiseless Pinions have proven so desirable that many motor and machine tool builders now supply the New Process Pinion as a standard part.

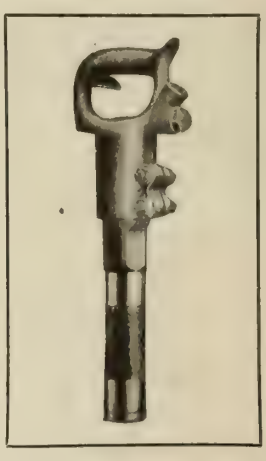
IMPERIAL PNEUMATIC CHIPPING and RIVETING HAMMERS

EFFICIENT
ECONOMICAL



The absolute safety and simplicity of transmitting compressed air, its wide range of profitable uses and the economies effected by its uses, give it an indisputable position of supremacy as a means of transmitting power for operating small portable tools.

Pneumatic tools are not delicate, complicated pieces of machinery, but positively simple, rugged little money savers, made to stand rough usage, yet maintain their efficiency.

In "Imperial" designs wearing parts are reduced to the reasonable limit of simplicity, and manufactured to give the greatest satisfaction.

No part of a plant equipment, representing the same investment, will do more to reduce labor costs, increase output and enlarge dividends than a good pneumatic tool equipment. We firmly believe that "Imperial" tools represent the very best sustained value; first costs, maintenance and operating costs being considered. They are thoroughly well designed, embody all practical up-to-date improvements and give very exceptional efficiencies. These features have won for Imperial tools their present favored position.

RENOLD PATENT SILENT CHAINS

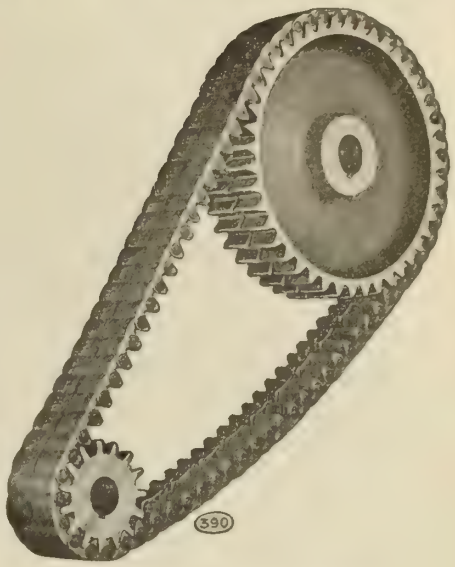
What Users Think

MONTREAL, Feb. 8, 1909.

Messrs. Jones & Glassco, Montreal.

RE RENOLD SILENT CHAIN DRIVE.

GENTLEMEN,—In reply to your enquiry of Jan. 30th, I may say that the Renold Silent Chain Drives we have installed are giving every satisfaction.



Our first drive was installed to replace a 12 in. belt which was giving us trouble on account of short centres ; this chain has run continuously for four years without the slightest trouble.

Our second drive was installed on a mixing machine doing heavy duty and which had previously broken up two sets of spur gearing ; this chain has run over three years with no sign of wear yet.

Our third drive was installed on a calendering machine after breaking two sets of helical gears and this has been so successful that we are now installing two more similar drives.

I would be perfectly willing to make an appointment with any person genuinely interested and show him the drive in operation.

The above comes from one of the largest manufacturers in Montreal and is signed by the Mechanical Superintendent. Up to the present (1911) these drives have not received repairs of any kind.

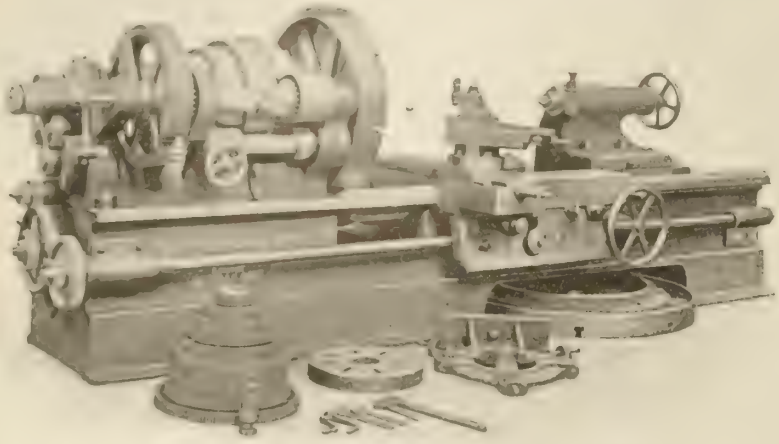
By the TROPENAS CONVERTER PROCESS

We beg to announce that owing to the growth of our steel foundry business we are giving up the manufacture of grey iron castings, and in future by specializing hope to give still better satisfaction.



When new improvements at present under way are finished, we will have the most modern and best equipped steel foundry in Canada for the manufacture of steel castings up to 1,000 lbs. weight.

Making Milling Cutters to Secure Greatest Efficiency*

By A. L. DeLeeuw

Present-day Practice Shows that Better Results Can be had From Milling Cutters by Increasing the Tooth Space and Depth. They Have a Number of Points in Their Favor Among Which are Less Consumption of Power, a Greater Amount of Work Done for One Sharpening and a Greater Number of Possible Sharpenings per Cutter. A Change in the Form of Chip Breaker Made it Possible to Use Cutters With Chip Breakers for Finishing, as Well as for Roughing. It was Found Advisable to Use a Special Kind of Key, Here Described, for Heavy Work. Finally, This Paper Describes a New Style of Face Mill and What is Called a Helical Mill.

THE amount of metal which a machine tool can remove in a given time is limited by the strains caused by the cut. Great hardness of the material to be cut, or a dull tool, will severely strain the machine and so reduce the section of the chip, even if the machine

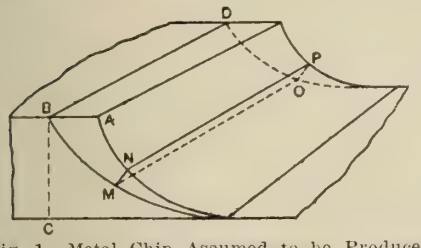

Fig. 1.—Metal Chip Assumed to be Produced by Milling Cutter Without distortion.

is rigidly constructed and well supplied with driving power. It is therefore of the greatest importance to analyze carefully all the conditions which cause heavy strains so that they may be obviated or reduced to the lowest possible limit.

This limitation of the cutting capacity occurs in all metal cutting machines, although to a varying extent. While it is possible to increase the driving power of most machines ad libitum, and almost any amount of metal can be put into machine elements to give them rigidity, there are certain classes of machines where practical considerations limit such increase of power and strength. This is especially true in machines where the main elements have to be adjusted and handled with great frequency. The knee-and-column type of milling machine owes its success, to a large extent, to the ease and rapidity with which it can be manipulated and it is doubtful if it will ever be possible to increase the dimensions of the parts much beyond the present sizes, without losing the benefits of the peculiar construction of this type of machine. In order to increase the capacity of this type of milling machine, it becomes necessary to reduce the strains set up by the cut and there are only two elements which can be modified to accomplish this result. These are the hardness of the metal to be cut and the cutting qualities of the milling cutter. As it is impossible to control the first of these the only avenue left for improvement leads in the direction of the milling cutter.

The action of the ordinary milling cutter is not a true cutting action, as it is commonly understood. By a true cutting action is meant the driving of a wedge-shaped tool between the work and the chip and although this definition is not based on a generally accepted meaning of the term it is believed that it expresses fairly well what most mechanics understand by cutting. Practically all milling cutters have their teeth radial and this, of course, excludes the possibility of driving a wedge between chip and work. The tooth compresses the metal until it produces a strain great

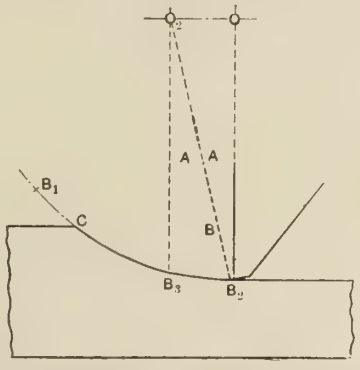

Fig. 2.—Diagram Illustrating Action of Milling Cutter.

enough to cause a plane of cleavage at some angle with the direction of the cutter. It then begins to compress a new piece, push it off, and so on. This at least seems to be the action of the cutter, judging by the form of the chips. These chips are in the form of needles or small bars.

The chip taken by a milling cutter varies very materially from those taken by a lathe or planer tool. These latter tools make chips of uniform section, whereas the section of a milling chip increases from zero to a maximum.

Fig. 1 shows a milling chip as it would appear, if no compression or distortion took place. The proportions are very much exaggerated, so as to bring its typical shape clearer into view. The width AB at the top is equal to the feed per tooth. The height BC is the depth of cut. The length BD is the width of cut. The section MNOP, shown half way on the chip, is a normal section and a measure of the amount of work which was done at the time the cutter passed the point M.

Fig. 2 shows the action of a milling cutter, with centre O, when the cutter is rotating and the work is feeding at the same time. The tooth AB sweeps through the path BC. When the point B has reached the position B_1 a new tooth starts cutting. By this time O has advanced to position O_2, and the new tooth A_2 B_2 is not yet in a vertical position, when the point B_2 touches the work, When the cutter revolves, this point B_2 must penetrate into the work and compress the metal of the work. The result will be spring in the arbor. When this spring has assumed certain proportions, the blade or tooth begins to remove a chip. This may be assumed to take place in the position B_2, the tooth simply gliding over the work from B_2 to B_3. This action must necessarily be very harmful to the cutter, and, it was believed that this perhaps more than any other action of the cutter, caused its dulling. It would be especially severe with light cuts, as a relatively small amount of spring would allow the point B_2 to travel through a large arc. It would be quite possible that a tooth should fail entirely to take a chip, and that the succeeding tooth would take a chip of double the amount.

This peculiar action of the milling cutter is inherent in its construction and

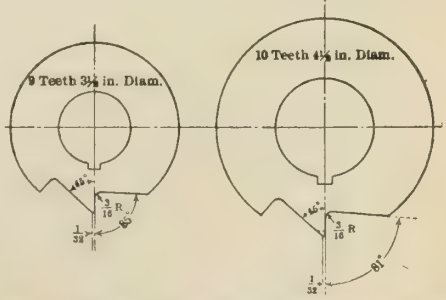

Fig. 3.—Form of Spiral Milling Cutters Now Used by the Cincinnati Milling Machine Co.

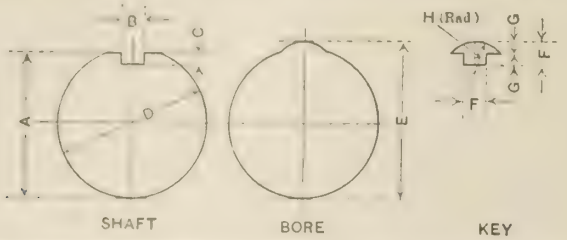
cannot be avoided. The question then is how to minimize these harmful results.



Another feature, which limits the ability of a milling cutter to remove metal,

* Read before the A. S. M. E., New York.

is the proportion between the chip to be removed and the amount of space between two adjoining teeth. Such a limitation does not exist with lathe or planer tools, where the chips have unlimited space in which to flow off.

That this proportion between chip and chip space actually [illegible] a cutting

ters and special gangs. The standard diameters are 3½ in. and 4½ in. The 3½ diameter cutters are made with nine and the 4½ diameter cutters with ten teeth which corresponds to a spacing of about 1¼ in. The point of the tooth has a land of 1/32 in., and the back of the tooth forms an angle of 15 deg. with the

Fig. 4. Shape and Dimensions of Keys Used for Milling Cutter Arbors.

[illegible] radial line. The chip space is approximately four times as great as in the usual standard cutter of the present time and is formed with a 3-16 in. radius at the bottom.

Proper Sized Arbors.

Though not directly connected with the foregoing, attention should be called to the fact that the present practice calls for arbors which are too small. In the cutters shown here, the 3½ in. cutter is made with 1½ in. and 1¼ in. arbor, and the 4½ in. cutter with 1¼ in. and 2 in. arbor.

It is often very difficult to remove cutters from an arbor after they have done heavy work. It is frequently necessary in such cases to press the arbor out of the cutters. This sticking of the cutter is caused by the burring up of the key and often the keyway in the arbor. For this reason, keys are used for gangs of cutters as shown in Fig. 4. A flat is milled on the arbor, and the keyway milled central with this flat. The flat portion of the key presses against the flat part of the arbor, and this effectively prevents burring. Cutters which are held on the arbor with such a key can always be very readily removed, even after prolonged and hard work. The keys are made out of a piece of round stock, grooved at both sides and then sawed apart.

It was found that for roughing on the ordinary work in the shop a cutter with the wider spaced teeth would remain sharp for a longer period, notwithstanding that feeds had been increased. The system of the Cincinnati Milling Machine Co. requires all gangs and cutters to be re-sharpened after a lot of pieces have been milled. It used to be necessary, at least on the larger lots, to re-sharpen the gang once and sometimes twice for the one lot, or, if this was not deemed advisable, the feed had to be reduced for at least part of the pieces, in order to make the cutter last during the entire lot. In all cases where the wide-spaced cutters were used, the entire lot was run through without re-sharpening the cutter or reducing the feed; and it should be kept in mind that this feed was from 25 to 100 per cent. greater than previously used. There is no case on record where the cutter or gang was dull at the end of the lot, so that our observations as to the endurance of the cutters are incomplete. However, it is perfectly safe to say, that in all cases under observation the cutter maintained its sharpness longer; that in a great many cases double the amount of work could be done without re-sharpening, and that there is good reason to believe an even greater gain than this was obtained.

A further advantage is, that as these cutters have approximately only half the number of teeth of what is now considered a standard cutter, the time for re-sharpening is only half as much.

It was pointed out that the ratio of pitch to depth is practically the same as in the present standard cutter, so that the depth of tooth is practically doubled and this cutter can be sharpened much more frequently than the present standard cutter. Consequently the life of the cutter has been much increased, probably more than doubled.

A glance at the drawing of these cutters gives the impression that the teeth are weak and the writer has watched this feature with great care. The cutters themselves, however, do not give this impression; on the contrary, they look stout and well proportioned. They have been subjected to the heaviest class of work and many times were purposely abused in order to find their weak points; yet there is no case on record that any of them have broken although they have been used for more than two years and all breakages of cutters are carefully noted. On the other hand, breakages of the old cutters are not at all infrequent.

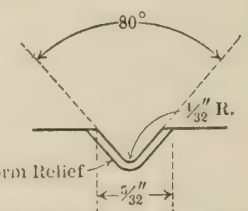

Fig. 5. Chip Breaker, Double Size.

Though these cutters are capable of removing metal more rapidly than the older type of cutter there are many cases where this feature cannot be taken advantage of, as, for instance, where

light work is to be done or a small amount of stock to be removed. In such cases, however, the metal is removed with less power and consequently with less strain on the machine and the life of the machine is lengthened without limiting its output.

Smooth Cutting.

With the wide spacing of the teeth it may seem that there would be cause for apprehension as to the action of the feed. It seems as if the feed would be liable to act with jerks. This, however, is not the case. On the contrary, the feed is smoother and there is less of a jerk when the cutter first strikes the work, probably because there is less spring in the arbor and less tendency for the cutter to ride over the work, as will be explained later in connection with the description of cutters.

In connection with this it is interesting to note that when cast iron is milled by these wide-spaced cutters, it appears to be very soft and when the same piece is milled by an old style cutter, it appears to be much harder. When using wide-spaced cutter, there is a notable absence of jerking, chattering and of the peculiar singing noise which is so often noticed on milling machines.

There is, of course, a difference in the hardness of different pieces of cast iron, and many recommendations as to the proper feeds and speeds for milling cast-iron work, made by the writer for his company, were looked at askance. The impression seemed to prevail that feeds and speeds which were possible on American iron, were out of the question on European iron, (especially English and German); and again, that feeds and speeds proper for western American iron were not suitable for eastern iron. To test the truth of the matter, a number of bars of cast iron were obtained from different foundries in America, England, France and Germany. These bars covered a great many mixtures and makes, and the difference between English and American, or German and American iron, or between eastern American and western iron, was found to be no greater than that between different specimens of western American iron. Even German Spiegeleisen, famous for its hardness, cut just as freely as soft western iron, and required but little more power. However, it did require more clearance, wide spaces, and a low speed.

These wide-spaced cutters were originally intended for roughing operations only, but the very satisfactory finish obtained when roughing led to the use of the cutters for finishing also. If there is any difference at all in the finish produced, the advantage is on the side of the wide-spaced cutter. The fact that this wide-spaced cutter will cut a greater number of pieces without dulling means, of course, that the average finish of an entire lot is better.

Chip Breakers.

It is generally believed that for finishing alone a milling cutter should be used without chip breakers, the effect of the chip breaker being to scratch the surface. To overcome this trouble, chip breakers are made as shown in Fig. 5 with clearance at both corners. This prevents the tearing up of metal with result that a cutter with these chip breakers produces as good a finish as one without chip breakers.

It should be pointed out that this form of chip breaker has an advantage also for roughing cuts. The point of the

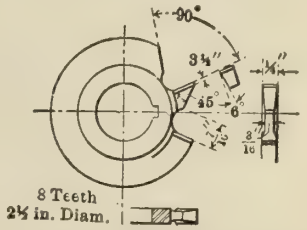

Fig. 8. Details of New Type of Side Mills.

cutter, where the unrelieved side of the chip breaker drags over the work, is the first point to give out. Making the chip breaker with clearance on both edges prolongs, therefore, the life of the cutter.

One of the great advantages of this form of chip breaker is, that one gang can be used for both roughing and finishing. A great many, if not most milling operations, call for two chuckings, one for roughing, and one for finishing. This will be found to be necessary wherever much metal is to be re-

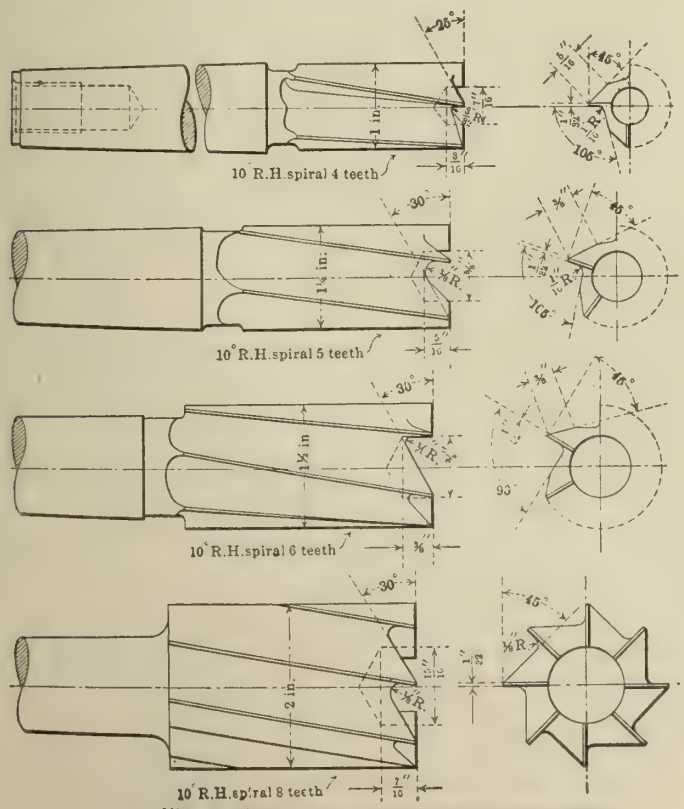

Fig. 6—New Type of Taper Shank End Mills.

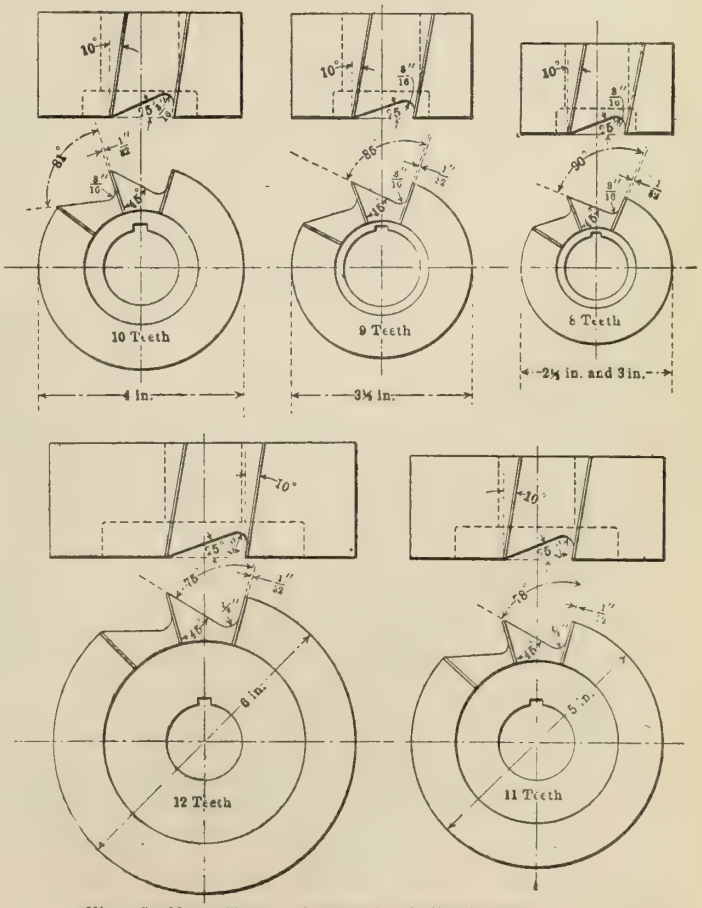

Fig. 7—New Type of Spiral Shell Cutters.

moved, on account of distortion, caused by the cut, the heavy clamping required, heating, spring of arbor or fixture and the unbalanced condition of the work after the scale has been removed on the side. In order to do the roughing as rapidly as possible chip breakers are required; and in order to get proper finish, it has heretofore been necessary that the finishing gang be without chip breakers. It paid, therefore, to have two gangs whenever the number of pieces to be milled was sufficiently large, but this involved considerable extra expense for cutters. The new form of chip breaker, however, permits using one gang for both finishing and roughing.

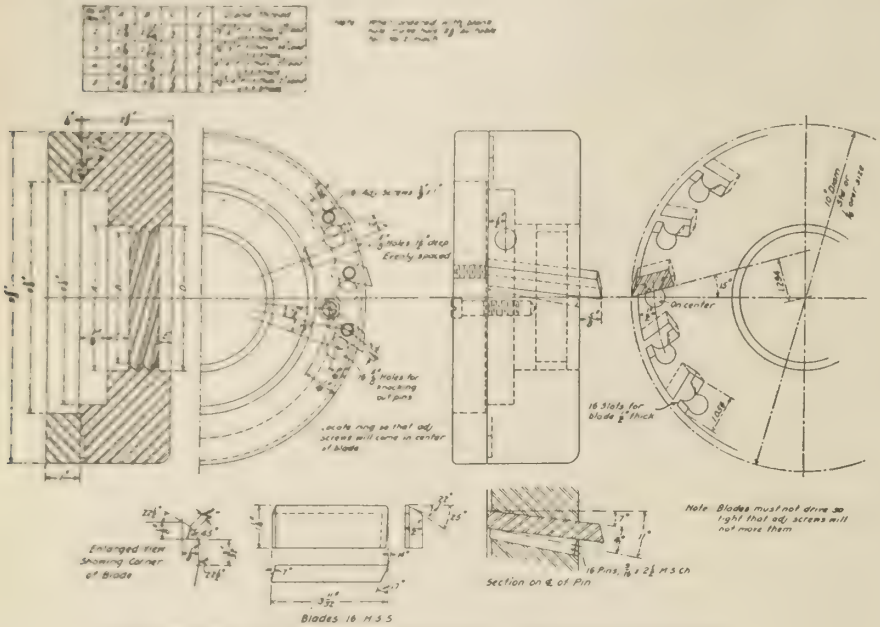

Fig. 10—Ten-inch Blade Face Mill for High Power Machines.

It is a common belief that better finish can be obtained with teeth closely spaced, but experience with the wide-spaced cutter shows that there is no ground for this belief. The grade of finish may be expressed by the distance between successive marks on the work. These marks are revolution marks and not tooth marks. It is practically impossible to avoid these revolution marks. They are caused by the cutter not being exactly round or quite concentric with the hole, by the hole not being of exactly the same size as the arbor, by the arbor not being round, by the straight part of the arbor not being concentric with the taper shank, by the taper shank not being round, or of the same taper exactly as the taper hole in the spindle, by this taper hole being out of line with the spindle, by looseness between the spindle and its bearings, etc. Each of these items is very small in any good milling machine; yet the accumulation of these little errors is sufficient to cause a mark and this mark needs to have a depth of only a fraction of a thousandth of an inch to be very plainly visible. As these marks are caused by conditions which return once for every revolution of the cutter, it is plain that the spacing of the teeth can have no effect on the distance between them, and, therefore, on the grade of finish.

To test this still further, two cutters of the same size exactly were placed side by side on an arbor. The cutters were ground together so as to be sure they were of equal diameter and they were ground on the arbor so as to be sure that the error would appear simultaneously for both cutters. A block of cast iron was finish-milled with these cutters in such a way that each cutter would sweep half the width of the block. The same number of marks appeared on both sides of the block, and these marks were exactly in line with each other, as might have been expected. The grade of finishing was the same for both sides. It was neglected to mark the two sides of the casting to show which cutter was operating. After this test, all of the teeth but one of one of the two cutters were ground lower, so as to be out of action entirely, leaving only one tooth of the one cutter operative. Another cut like the first one was taken over the same block, and again the finish appeared the same on both sides. There was a difference of opinion between different observers as to which side was cut by the single tooth. By close observation, however, a difference could be detected when light fell on the work in a certain direction, under which conditions one side showed more gloss than the other. Straightness, flatness and smoothness to the touch was exactly the same for both sides, notwithstanding that one cutter had one tooth only and the other fourteen teeth. Though it is not recommended here to use cutters with one tooth only for finishing, the foregoing test showed plainly that there is no merit in fine spacing. Attention is again called to the fact, that even though the finish on a single piece might be better with more teeth in action, the average finish for an entire lot of pieces is better with less teeth.

End Mills.

Fig 6 shows the end mills which are now considered standard by the Cincinnati Milling Machine Co., and which fill practically all requirements. They are made in sizes of 1 in., 1¼ in., 1½ in. and 2 in. in diameter, the smallest with four, and the largest with eight teeth It will be noticed that in order to preserve the strength of the teeth it is necessary to mill the back of the teeth of the three smaller sizes with two faces. A number of tests have been made with these cutters, but no comparative tests as to power consumption. Their action is remarkably free. This was clearly demonstrated by the following experiment: A 2 in. taper shank end-mill milled a slot 1 1-16 in. deep in a solid block of cast iron at a rate of 6 in. per min. The block was clamped to the table of the milling machine and the knee was fed upward. Under these conditions the chips did not free themselves from the cutter but were carried around and ground up. The cutter was cutting over half its circumference. These two conditions combined make the task for the milling cutter about as difficult as imaginable. There was, however, no sign of choking and the power consumption was not higher than it would have been with a spiral mill under ordinary canditions. The same cutter would remove from the end of the casting a section 1½ in. wide and 1½ in. deep. Under those conditions, the chips were rolled up in pieces much like the chips obtained from a broad planer tool, when taking a finishing cut. This cut was taken with a feed of 11 in. per minute. Another similar cut, but 1 in. and 1⅛ in. in section was taken with a feed of 33 in. per minute. Similar though much lighter cuts were taken with ordinary end mills, and in the same piece of cast iron. Again the cast iron seemed to be very hard, and became glossy when cut with an ordinary cutter, but appeared to be soft when cut with the wide-spaced cutter.

Fig. 7 shows the shell end mills of the wide-spaced type, which are now considered standard for their use by the Cincinnati Milling Machine Co. Figs. 8 and 9 show the side mills.

Face mills have also undergone a gradual evolution and they are now used by the company in catalogues, though not made by them for the use of customers, as shown in Fig. 10. Fig. 11 shows a cutter of a design now generally considered to be standard. In this latter design, the blades are spaced 1 in. apart, or approximately so; they are

set radial, and have no means to keep them from pushing back except the regular holding means. The wide-spaced faced mill, on the other hand, has the blades spaced 2 in. apart. They are set at an angle of 15 deg. with the radial line, and are backed by a backing ring with a set screw for each blade. These set screws allow the blade to be adjusted, besides forming a stop against upward movement under pressure. A face mill may be considered as a planing tool moving in a circular path. The cutting edge, therefore, is axial and not radial. To set the blades at an angle with the axis does not produce rake. The wide-spaced face mill shown here has rake, because the blades are set at an angle with the radial line.

It will be noticed that the blades are set at an angle with the axis. It will further be noticed, in the enlarged view of the blades, showing the rounded corners, that the corners are not provided with a round, but rather with three faces, which together approximate a curve. It is to offset the effect of this round that the angle with the axis is introduced.

However accurately a milling machine may be built, the spindle is not exactly at right angles with the table. The amount of variation exists. Besides, this variation is liable to become greater when the machine wears. The result is, that when feeding in one direction the leading teeth of the cutter dig deeper into the work, leaving the other side of the cutter entirely clear, but when feeding in the opposite directian the opposite takes place, which makes the teeth drag over the work. In order to provide the teeth with clearance, the back end of the tooth is ground away at an angle of three to five degrees.

It will further be noticed, that there is a land of 3-16 in. only where the blade is straight. It is the excess of width of the cutting blades which is liable to cause chatter. Strange as it may seem, this chatter is more pronounced with a light than with a heavy cut. It is not meant that there is actually chatter, but merely that when there is a tendency to chatter, the tendency is greater on a lighter cut. The cause is that the tooth does not enter the work but tries to ride over it. When the cutter has been lifted sufficiently, the pressure becomes great enough to make the blades enter. The next blade meets the same difficulty about entering, is lifted again, and so on. This action causes a series of radial chatter marks and is very much worse with wide blades than with narrow ones; and again very much worse with a large number of blades than with a few. A 3-16 in. land proved to be an acceptable compromise, as a wider land would quickly dull the cutter, even if it did not make a chatter mark, while a narrower land would have the tendency to produce a scratchy finish.

Helical Cutter.

In Fig. 12 is shown details of a helical cutter. These cutters consist of a cylindrical body, with two or three screw threads wound around them, the threads being of a section clearly indicated in the engraving. The helix is wound around the body with an angle of 69 deg. with the axis. The diameter is $3\frac{1}{2}$ in., and the lead of the helix $4\frac{1}{4}$ in. They are made in two styles, either single, or as interlocking right and left hand cutters. They are made with a rake of 15 deg. and clearance of 5 deg. when used for steel, and with a rake of 8 deg. and clearance of 7 deg. when used for cast iron. Their most distinguishing feature is, that they push the chip off in the direction of the axis of the cutter, or at right angles to the feed. The power consumption is extremely low for steel, but does not show up so favorably for cast iron. A roughing cut in steel requires only about one-third the power of an old-style spiral mill. Another distinguishing feature is, that this cutter does not make revolution marks but tooth marks. As a result, a much coarser feed can be used for finishing. A cutter with three teeth will allow of a finish three times as fast as an ordinary spiral mill. Still another feature of this cutter is the entire absence of spring in the arbor when cutting steel. It is possible to take a finishing cut over a piece of steel, then return the work under the cutter and let the cutter revolve any length of time without producing a mark.

It was originally thought that a single cutter of this description would do well for finishing, but not for roughing, on account of the excessive end pressure on the spindle, and the interlocking cutter was made to obviate this end pressure. However, it was found that this end pressure, though perceptible, was no disturbing element. Cuts which required 80 amperes with the interlocking cutter, required 85 amperes with the single cutter. In order to see if continued use of the single cutter would cause increasing friction at the spindle end, a great number of cuts were taken in as rapid succession as it was possible to adjust the machine for the next cut.

The fact that there is no spring in the arbor makes it possible to use the milling machine without braces in a great many cases where they would otherwise be needed.

It was first believed that these cutters would work best at a high speed; but it was found that this was not the case. They produce the best results when run at the same number of revolutions as the ordinary spiral mill.

The writer believes that the remarkably low-power consumption is due to what might be called "virtual rake,"

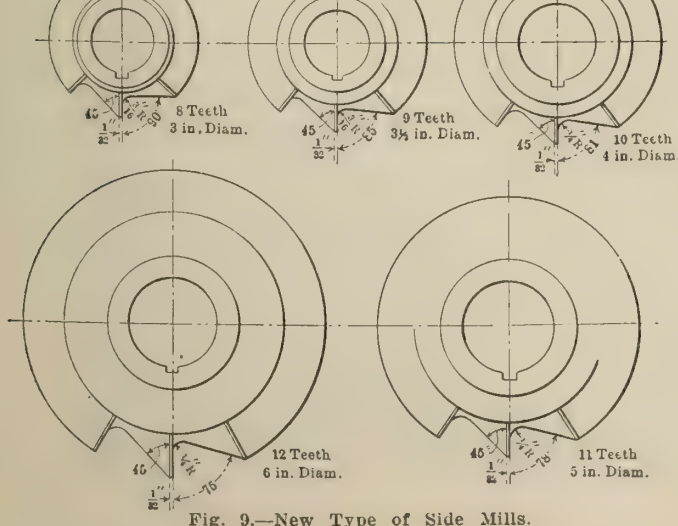

Fig. 9.—New Type of Side Mills.

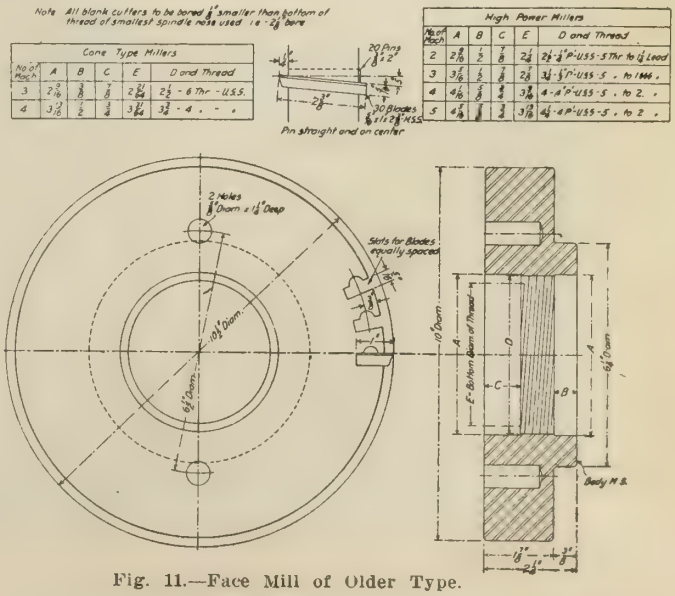

Fig. 11.—Face Mill of Older Type.

which is an angle depending on the angle of rake, and on the angle the thread or tooth makes with the axis. This virtual rake becomes a small angle when the actual rake is small. This is the case with the cutter as used for steel where the actual rake is 5 deg. Where, however, the angle of rake approaches 90 deg., the influence of the helix becomes very much less pronounced; and, if the actual rake were 90 deg. the influence of the spirality would be zero, in other words, the virtual would equal the actual rake. This may explain why the saving in power consumption is not so pronounced when cutting cast iron. It is believed that this saving of power would be equally great with cast iron as with steel, if the same virtual rake could be obtained, and this supposition was borne out by a few tests made on cast iron with a helical cutter ground for steel.

Another reason which suggests itself to the writer as to why the helical cutter shows less saving in power on cast iron than on steel, is the result of a series of tests made on cast iron and steel with spiral mills with and without rake, the rake being in all cases 9 deg. These cutters showed improved efficiency for steel and cast iron, but much more for the first than for the latter. A cutting tool must detach the chip from the work, bend the chip and at least partially break it up. When cutting steel, the radius of curvature of the chip becomes greater with increased rake and the extent to which the chip is broken up becomes less. Cast iron will stand much less bending before breaking, so that, even with increased rake, the chip is still broken up as before, and no saving in power can be effected in this part of the process.

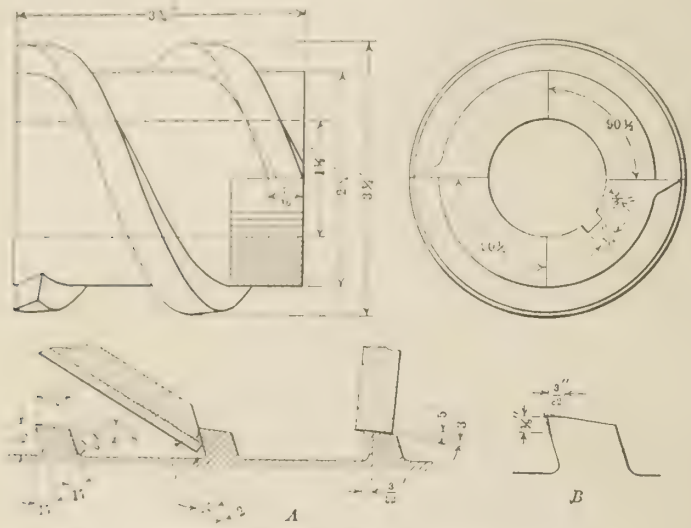

Fig. 12. Details of New Type of Helical Cutter.

REBORING CYLINDER.

By G. D. Keith

The Hall Engineering Works, Montreal, recently rebored a low pressure cylinder of 15 in. diameter and 18 in. stroke at the Dominion Textile Company's (Merchants' Branch) Cotton mills, Montreal. A portable boring gear, the property of the Hall Engineering Works was used, it being shown in operation in the accompanying illustration.

Steam was shut off the engine at 7 p.m. Thursday. The cylinder cover was removed and the piston and piston rod taken out. The boring gear was then placed in position, as shown, and reboring was commenced on the following morning. Three cuts were taken out of the cylinder, increasing its diameter $\frac{3}{4}$ in. The cylinder was finished and a new piston fitted, all coupled up, and a steam trial taken at 3.30 p.m. the following Sunday when everything worked satisfactorily. This work was therefore completed between Thursday at 7 p.m. to Sunday at 3.30 p.m.

Reboring Cylinder, Hall Engineering Works, Montreal.

EXTENSION DRILL MADE OF PIPE.

A serviceable extension drill may be made from a section of brass or iron pipe in the following manner: Take a piece of pipe, the internal diameter of which is the same as the diameter of the hole to be drilled. With a cross-peen hammer make two dents opposite each other about one and one-half inches from the end of the pipe. Into this end drive the twist drill first, grinding the end flat. A tap may also be driven in this fashion successfully.

TO MAKE BRAZED JOINT.

If occasion should arise when it is desirable to make a good clean brazed joint, the metal should be carefully cleaned, heated to a bright red, and then covered with the flux of the following formula: One pound of boric acid, four ounces of pulverized chlorate of potash, and three ounces of carbonate of iron.

A modern grinding wheel used on a modern machine by an operator with a good knowledge of grinding is just as surely a milling cutter as if it were made of steel. Its cutting surface consists of millions of small, sharp cutting teeth and each tool that comes in contact with the work cuts off a chip in the same manner as the tooth of a milling cutter.

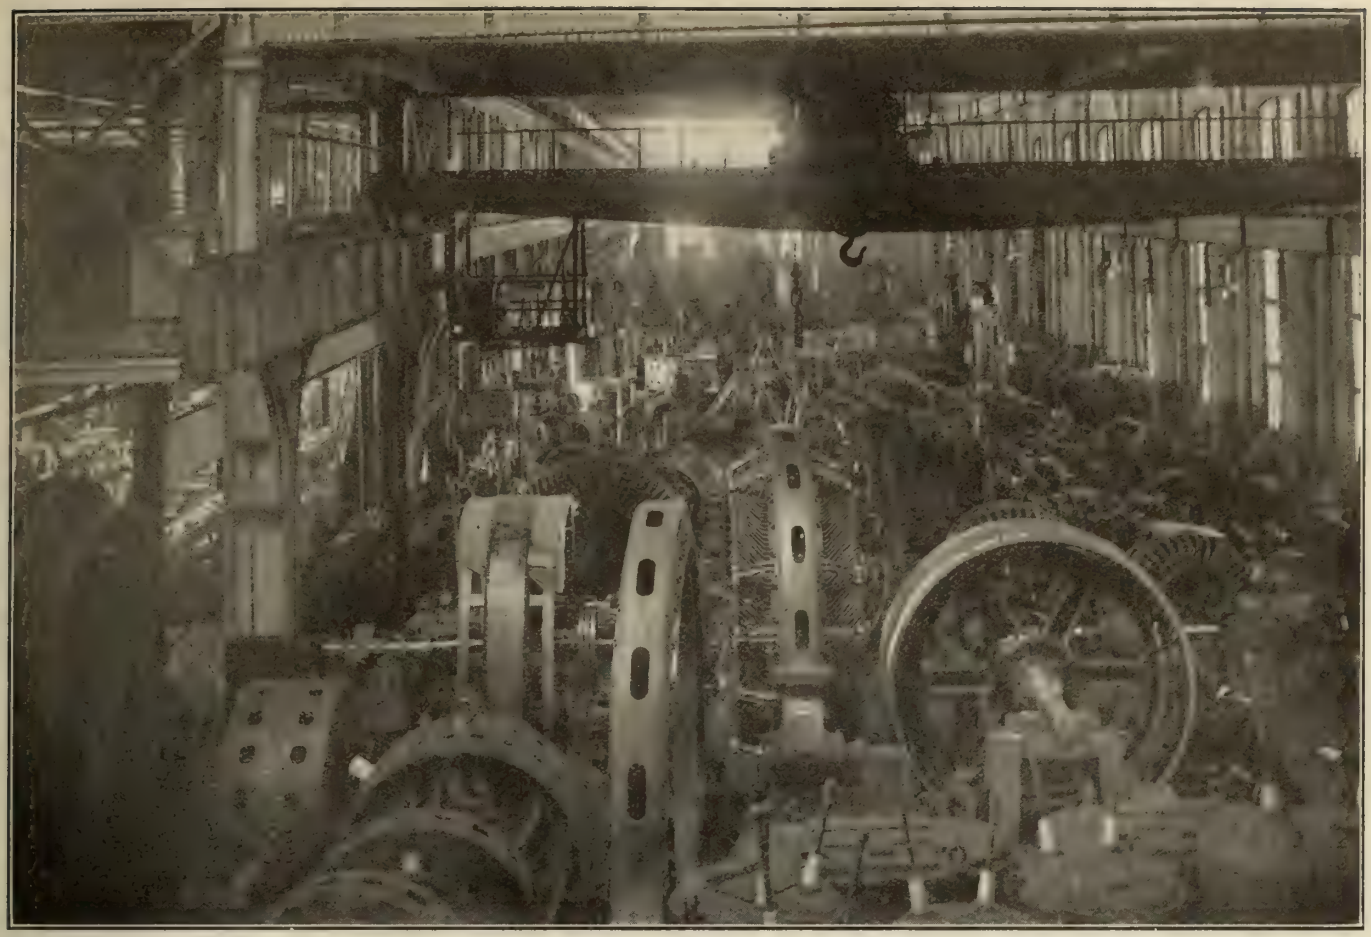

Fig. 3—The interior of one of the shops of the Canadian Westinhouse Co., Hamilton, taken April, 1911. The large amount of work under construction gives an idea of Canada's industrial expansion.

Enlarged Works of Canadian Westinghouse Co., Hamilton

An Interior View of One of the Canadian Westinghouse Shops Gives an Idea of the Enormous Amount of Work Under Construction by the Canadian Electrical Companies, and Also of Canada's Industrial Development. The Reason for Enlarging the Works is Therefore Obvious.

IN Fig 1 is shown the plant of the Canadian Westinghouse, Hamilton, as it will appear when the additions are completed. The works are conveniently located beside the main line of the G.T. R., sidings running therefrom to the various buildings for the receipt of material and shipment of product, while on another side of the plant, connection is made with the C.P.R.

The buildings are of the most modern approved type of fire proof construction, being of brick, reinforced concrete and steel. Fig. 1 shows the brake plant at the extreme right; the main buildings in the centre of the plan are devoted to the manufacture of electrical apparatus; and those on the extreme right consisting of pattern shops and foundry supply the needs of the brake and electrical departments in both brass and iron castings.

Building Plans.

In laying out the manufacturing buildings, two cardinal points were kept in view:—Each department might be capable of extension, and that the progress

Fig. 2—A 10,000 k.w. generator built by the Canadian Westinghouse Co., Hamilton, for the Canadian Niagara Power Co.

of material from the raw to the completed state, should, as far as possible, be in a continuous direction. This purpose, and the carrying on of operations with dispatch is facilitated by traveling cranes and an industrial railway.

Recent Additions.

The Canadian Westinghouse Co., to keep pace with the demand for electrical machinery in Canada, have found it necessary from time to time, to make extensions to their plant, the most recent of these, included an added space of 11,580 sq. ft. of storage, and 14,000 sq. ft. manufacturing capacity, besides increasing the area of the testing and shipping departments.

The foundry building will be more than doubled in size, which also means additional cupolas, core ovens and improved facilities for the handling of of foundry material, adding a floor space of 22,800 sq. ft.

The same plan of design and fire proof construction as first used, has been followed in all the additions, the only variation being that heavier steel work has been found necessary to serve increased crane carrying capacity, on account of the greater size of the units now being turned out.

The large interior scene, Fig. 3, is an interesting view of one of the machine shop aisles, with apparatus in various stages of construction. Fig. 2 shows the stator and bedplate of one of the Westinghouse type of 10,000 k.w. generators.

High-powered men like high powered engines do their work without making any noise.

APPLYING SCIENTIFIC KNOWLEDGE.

One of the common faults of some educated men is that they make little or no application of the scientific facts learned in school to the everyday problems of life. Perhaps it is because they are literal-minded, the principles having for them only the applications mentioned in the book. For instance, two young men, both graduates of the same high school, some years after graduation got into an argument on whether the weight of a block of wood floating in a pail of water is added to the weightof the pail and water or not. Experiment, of course, showed that it is, whereupon the one who was worsted quoted the Archimedean law to the effect that a floating body displaces its weight of the liquid, and was inclined to doubt the soundness of the old Greek's dictum after making the test. The fact that the mere displacement of a liquid does not alter its weight had never before been made plain to him, and not until a pail brimming over was tested did he grasp the full significance of the law.—Machinery.

A man who signs himself as W. Keppel White is taking collections, renewal and new subscriptions, for the MacLean publications in the Maritime Provinces, without any authority. The assistance of any subscriber in locating this man will be appreciated.

CONVENIENT TOILET ROOMS.

There are dozens of machine shops, and some of them very large ones, in which a goodly sum could be saved each year were the toilet rooms more conveniently arranged in a place where they would be more available. In some shops it is necessary for a man to go down stairs; in other shops they must go up stairs and in a certain shop the men must travel nearly 200 feet to the toilet rooms and back to their work again. It takes considerable time to do all this traveling. Just hold a watch on several of the men and note how long it takes them to travel down stairs and get back to work again. Assume a certain number of trips made by each man during a day, multiply the number of trips by the time required, multiply this by the number of days in the year and figure out the cash value of the time thus consumed.—Ex.

While hot nickel solutions deposit nickel more rapidly than cold ones with a given voltage (i.e. the conductivity of the solution is increased), it is generally considered that the results are not enough better to warrant their use for the ordinary run of work.—Ex.

H. Etches, mechanical engineer and draftsman, has removed his office to 17 Bank of Hamilton Bldg., 34 Yonge St., Toronto. He was formerly chief draftsman with Carnegie Steel Co., Pittsburg; Waterous Engine Works, Brantford; Dodge Mfg. Co., Toronto, and Hanley & Miller, Toronto. His special line is designing special machinery, making working drawings,, and general designing work.

Mechanical Drawing and Sketching for Machinists*

By B. P.

A Series of Progressive Lessons Designed to Familiarize Mechanics With the Use of the Apparatus Necessary to Make Simple Drawings, to Encourage them to Realize How Important a Factor it is of Their Equipment, as Well as Being a Profitable Pastime.

IN drawing a circle say of 3 inches diameter, you will observe that on spreading out the arms to 1½ inches radius, the tool assumes a triangular shape. One result of this is your reaming out a large hole in the paper, and another is your poorly joined up line.

These troubles are aggravated as the circle to be described becomes larger,

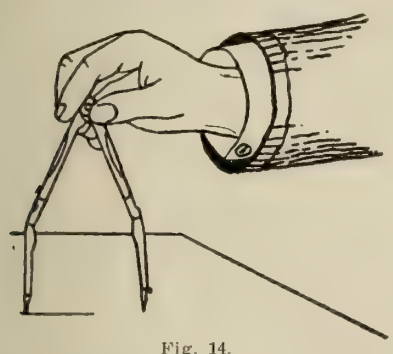

Fig. 14.

and to avoid them, care should be taken to adjust the movable arms so that, irrespective of the circle diameter, these will always be perpendicular to the paper surface, Fig. 14.

Drawing to Scale.

Drawings for the most part are made to a scale convenient to work from, other than full size; that is, the machine or its detail as drawn, bears some definite proportion to the finished manufactured product. This necessity of drawing to scale will doubtless be appreciated without further explanation. The number of views required to properly illustrate the object, determine together with the various size drawing sheets available, the proper scale to be used, consistent with easy, quick and intelligible reading of the drawing by the mechanic who has to work from it.

Figs. 15 and 16 show examples of 12 inch boxwood scales in general use, and should be divided to permit of drawings being made to ⅛, ¼, ⅜, ½, ¾, 1, 1½ and 3 inches per foot. The views shown should only be those absolutely necessary; multiplicity means duplication as a rule and lends itself to increased liability to error on the part of the draftsman, in addition to confusion in the shops. If a footnote therefore will obviate drawing another view, by all means adopt it. In preference to drawing dotted lines to represent internal or rear features, make sectional views to avoid possible misunderstandings.

Fig. 17 gives a suitable variety of lines to be used for the various purposes required in mechanical drawing, and Fig. 18 shows a system of sectional shading for the metals and materials in common use. It may be observed here

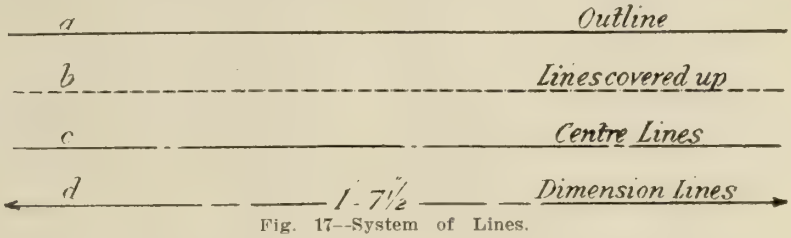

Fig. 17—System of Lines.

that for pencil drawings which are to inked-in or traced, no attention need be paid to line variety or sectional shading, as the foregoing refers altogether to inked drawings or tracings.

Drawings of casting and forging details for a machine should be drawn on separate sheets, the former it may be, to a smaller scale than the latter. Each detail should have its name, the number required per machine, and kind of material marked underneath, so that all the information pertaining to it may be in compact form and ready to the eye. It is usual to abbreviate the names of the various metals, saving as it does time and also space on an oftentimes crowded drawing sheet. The following abbreviations are universally adopted, and in any case quickly become familiar and understood by mechanics in any factory.

Cast iron—C.I.
Malleable iron—M.I.
Wrought iron—W.I.
Machinery steel—M.S.
Cast steel—C.S.
Brass—Br.

Finished surfaces are usually indicated by the letter f written across the line representing the particular surface to be treated. In case a piece is finished all over, mark "finish all over" in black ink below the title. Notes used in connection with a drawing should be connected by a wavy line and arrow to the part to which the note refers. Example of this will be found in the remark "⅛ inch keyway," Fig. 20. The sectional shading is spaced to please the eye and with regard to the area available.

Screw Threads.

Use the conventional method for representing screw threads except in the case of square threads. With the exception of V threads, always give character of thread. When other than standard threads are used, the threads per inch should be given thus: 16 P. I", and when a thread is left-hand, always call attention to the fact.

Arrangement of Dimensions.

Make your figures read from bottom and left-hand side of the drawing as you face it, and place them if possible so that they can be erased without interfering with the lines of the drawing. When dimensioning a sectional area break the section lines as shown on Fig. 21. Give over-all as well as intermediate sizes, and stagger as per Fig. 19. Radial dimensions may be as shown on Fig. 21. In writing or printing feet and inches, a suitable method is per example 7' 3¾" is shown. Restrict dimensions as far as possible to one view;

* Fourth of a series of an Instruction Course. A lesson will be given each month.

Fig. 15—12-inch Triangular Scale.

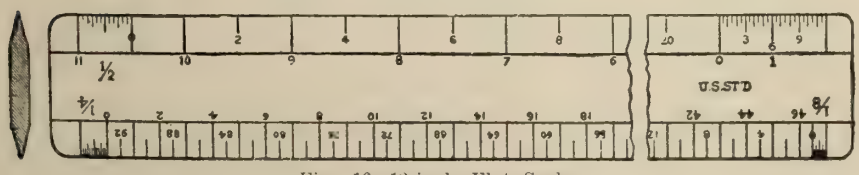

Fig. 16—12-inch Flat Scale.

work from centre lines and finished surfaces and avoid repetition; keep before you the capacity for handling work that the necessary machines in the shop have, and regulate the several parts to conform. Remember that other men have to work from your drawing, and that

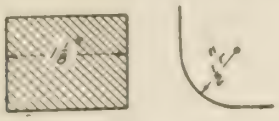

Fig. 21

therefore it is your duty to have it tell them clearly what they are required to make.

The writer is indebted to the Manual Training Magazine for cuts 19, 20 and 21, and some pointed and useful extracts.

"WHEEL COST" A SMALL ITEM.

In many grinding operations the wheel wear (the first cost) is a mighty small item of expense when compared with the actual cost of operation, in which we must figure the horse power consumed, labor, machine investment and the production.

In order to obtain a fair idea of the "cost of wheel," an accurate record was kept of a grinding operation on a 10 x 72" Norton Plain Machine. The work was grinding 35-point carbon open-hearth machinery steel shafts from the black stock, taking off a sixteenth of an inch, reducing from 1⅜" diameter to 1 5-16". A 15 x 2", 24-L. Alundum Wheel, was used and in ten hours' work it showed but .270" wear. The wheel was trued once at the start and once at the end of six hours. Work speed, 25 ft. a minute; wheel speed, 6,100 ft. a minute; table traverse 12 ft. a minute. That means a wheel cost of but a very few cents a week.

It is not good policy, therefore, when endeavoring to reach maximum grinding economy to let the purchase price of a grinding wheel stand in the way of a larger production. Instead of thinking "too much about 'wheel cost'" due consideration should be given to the other factors of cost—labor, which must be figured at from 60 cents to $1.00 an hour; the horse-power consumed in grinding; the production necessary to make the grinding machine investment a profitable one and the many advantages of rapid production. These are the factors that must be weighed carefully when purchasing grinding wheels. Compare them with the "wheel cost."

Economy consists in getting the right wheel for the work and operating it under the most favorable conditions, and the original cost of the wheel in most cases is too small an item to take into consideration.—Grits and Grinds.

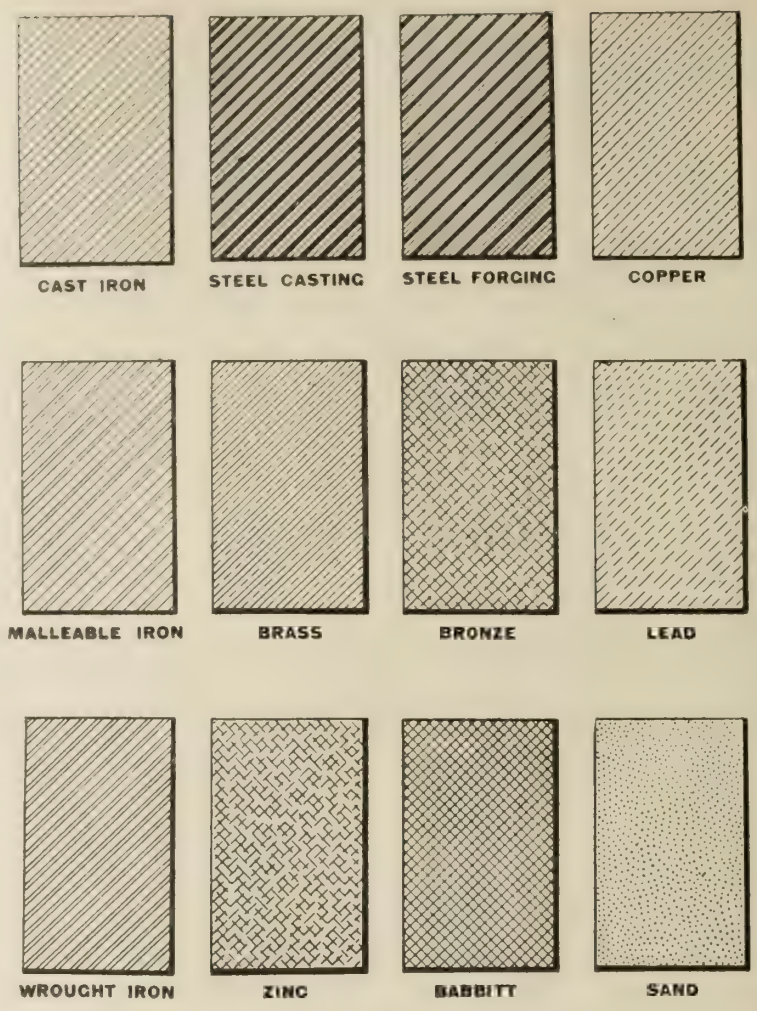

Fig. 18 System of Sectional Shading.

FIRM NAME CHANGE

The firm name of Foss & Fuller has been changed to that of the Foss and Hill Machinery Co. Mr. Henry W. Hill, late of the Wire and Cable Co., Montreal, is now an active partner together with Mr. George F. Foss.

CHANGE OF ADDRESS

The Standard Engineering Co., Ltd., late of 47 Wellington St. E., Toronto have moved to more commondious offices in Rooms 201, 210 and 211, the Dominion Exchange Building, 14 King street east.

Boiler Design, Construction, Operation, Repairing and Inspection*

By H. S. Jeffery

The Various Points in Connection With Boiler Practice Will be Clearly Taken up in This Series. The First Article Deals With the Boiler Shell, Including Repairing, Factor of Safety, Hydrostatic Test and Number of Courses. The Series Will be a Complete Text Book on the Subject of Boilers, and They Should be Preserved for Reference.

In Figs. 18 and 19 are shown two types of double riveted, double strapped butt joints. In Fig. 18 all the rivets are in double shear; both the inside and the outside welt strap being the same width, while in Fig. 19 one row of rivets is in double shear and the other row in single shear; the inner welt strap being of greater width than the

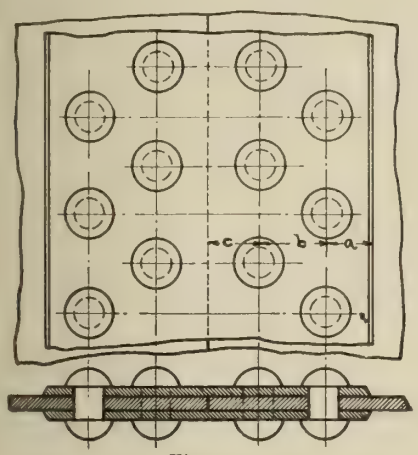

Fig. 18.

outer strap; also, the rivets in single shear are pitched twice as great as the rivets in double shear.

To compute the strength of the riveted joint, Fig. 18, first find the efficiency of the net section of plate and then the efficiency of the rivets, and the

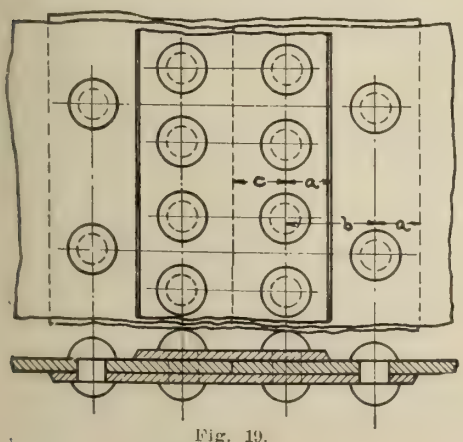

Fig. 19.

lower value of the above will be the efficiency of the riveted joint. Inspection of Fig. 18 shows that the pitch of rivets in both the inner and outer rows of rivets is the same, and accordingly, the efficiency of the net section of plate can be computed from either source.

Now, with the riveted joint, Fig. 19, the outer row of rivets, which is in single shear, are pitched twice as great as the rivets in the inner row, and which rivets are in double shear. Inspection of Fig. 19, and considering the foregoing remarks, shows that there is a minimum and maximum net section of plate, and that part of the rivets are in single shear and part in double shear.

In designing a riveted joint as shown in Fig. 19, or the triple riveted double strapped butt joint as shown in Fig. 20, which is only an extension of the double riveted double strapped butt joint, the riveted joint should be so designed as to make the weakest point the net section of plate of the maximum pitch of rivets.

A cause of failure of a riveted joint is the shearing of all the rivets. With a triple-riveted double-strapped butt joint, as shown in Fig. 20, this mode of failure need not be considered, but with a double-riveted double-strapped butt joint, as shown in Fig. 19, it must be considered.

Continuing the calculations of the riveted joint, Fig. 20, it having been already found that the rivet in single shear has an efficiency of 15.7 per cent., the efficiency of the rivets in double shear, must be found and added to the efficiency of the rivet in single shear. The shearing strength of the rivets in double shear is:

$$\frac{.7854 \times 4 \times 45{,}000 \times 1.85}{60{,}000 \times .5 \times 7.5} = 116.24 \text{ p.c.}$$

Distance Between Rows of Rivets.

15. The distance between the rows of rivets should at all times be sufficient to permit the rivets to be readily driven without cutting or disfiguring the head of the rivet when driving another rivet. The distance a, Figs. 18 and 19, which is the distance from the centre of the rivet hole to the edge of the plate, should be 1¼ times the diameter of the rivet hole. With rivets staggered, as shown in Fig. 18, the distance, b, between rows should not be less than 1½ times the diameter of the rivet hole, while the distance, b, of the riveted joint, Fig. 19, should be sufficient to permit the outer welt strap to be calked. The distance, c, of butt joint, especially the type of joint, as shown in Fig. 19, should be at least 1¾ times the diameter of the rivet hole.

Girth Seam Rivets Assistance.

16. With double-strapped butt joints, inner strap extended, as shown in Fig.

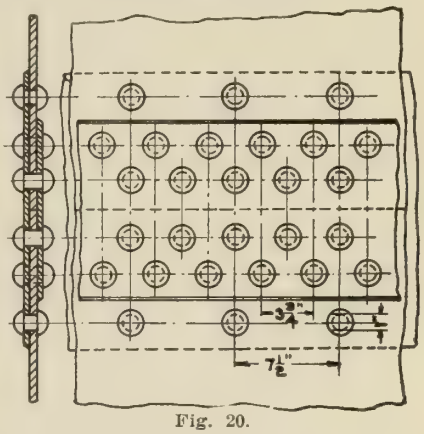

Fig. 20.

20, the net section of plate adjoining the girth seam will be less than the maximum net section of plate, this being shown by the letters a and b, Fig. 21. The net section a is not, however, weaker than the net section b, for to rupture the net section a, will require a number of the rivets in the adjoining girth seam to shear, the same being in-

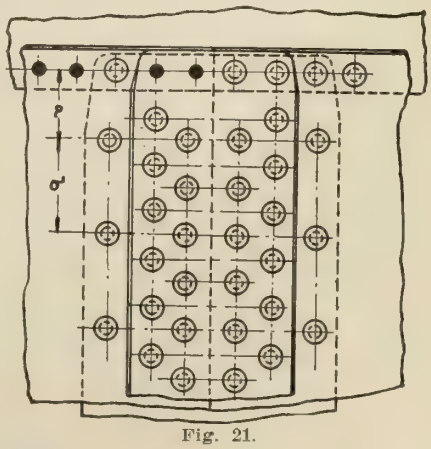

Fig. 21.

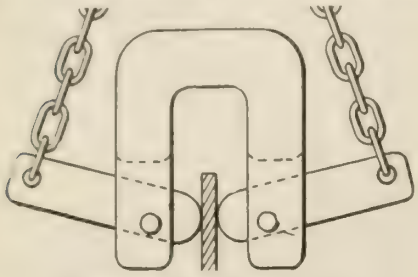
dicated by the rivets in black. Usually the strength of the net section a, and two rivets in the girth seam is sufficient to make the calculations show the efficiency of these parts greater than the net section b.



MACHINE SHOP METHODS AND DEVICES

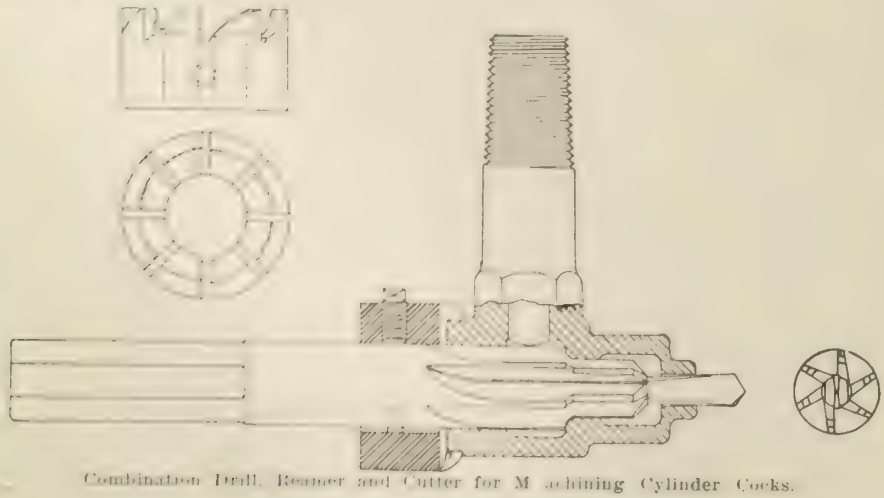
Unique Ways of Doing Things in the Machine Shop. Readers' Opinions Concerning Shop Practice. Data for Machinists. Contributions paid for.

PLATE HANDLING DEVICE.

By K Campbell

One of worst classes of stock to be handled, is plates All sorts of devices, clamps, etc., have been invented. The electro-magnet is used with great success but in many plants, especially the smaller ones a jib crane or a yard

Toggle Plate Lifting Device.



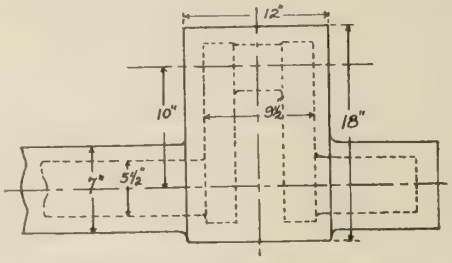
crane is used to advantage. In connection with these two methods, the device shown in the accompanying sketch can be used to advantage.

The two jaws are pivoted in a V clamp and form a toggle, gripping the plate very securely when unloading it. There is an appreciable saving of time in handling and there is no chance of the plate slipping as the tendency to slip causes the jaws to grip it more firmly.

COMBINATION DRILL, REAMER AND CUTTER.

By Efficiency.

The combining of operations is one means of securing greater efficiency in the shops In the accompanying illustration is shown a combination drill, reamer and cutter for machining cylinder cocks Instead of tooling, they are by means of it, bored, seated and faced, top and outside The operations are performed with the combination tool in one-eighth the time of that required by tooling out.



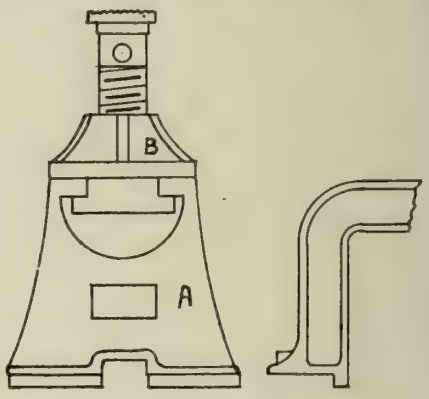
Combination Drill, Reamer and Cutter for Machining Cylinder Cocks.

FORGING VS. HIGH-SPEED STEEL.

By L. L. K.

It is sometimes debatable how much stock should be left on a forging to secure quick machining. Since the introduction of high speed steel it is found to give the greatest economy in production when little time is spent on the forging.

In the accompanying illustration is shown the dimensions of a forging which



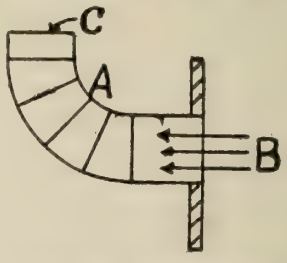
Rough Forging and Finished Shaft.

the writer took recently from one lying in an Ontario machine shop. The dimensions shown by the dotted lines were taken from a blueprint, which was furnished the workman. The forging was finished to size by using high speed steel.

LOCOMOTIVE JACK.

By Service.

In erecting a locomotive over a pit a special jack with a frame extending across the pits is a necessity. In the one here shown the part A is of steel and extends from rail to rail. B is brass. The jack can be used in any position along the base. Convenience in its



Locomotive Jack.

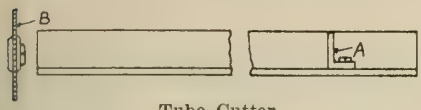
use, is the special feature which commends it.

FRESH AIR WITHOUT DRAFT.

By M. E. D.

The accompanying sketch the writer saw in use recently to obtain fresh air without a draft. Pipe elbows were used and were fitted into a board as shown. This board was the width of the window and about 6 ins. high. Air entered

Fresh Air Without Draft.



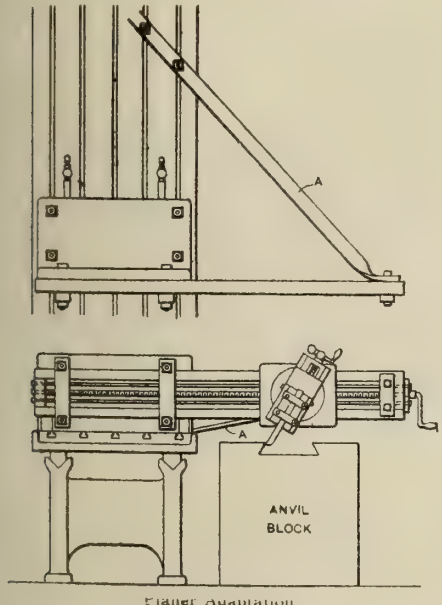
at B, the part A projecting inside. Four were used on each window, so that the amount of fresh air could be regulated. This was done by having caps fit over the pipe at C and removing as many as necessary. This device is especially useful for winter months or in a timekeeper's or cost office were a direct draft would soon mix up the papers.

TUBE CUTTER.

By Onlooker.

A simple arrangement for cutting tubes to length is shown in the illustration. An angle is used with A adjustable so that any length may be cut. B

is a saw. The angle is pressed forward by a simple foot arrangement, and is returned to place by three weights secured to it. In order to keep the angle perpendicular to the saw, the angle has



Tube Cutter.

three blocks which run in slots in the table. The weights are fastened to the angle just above the blocks. By this method quantities of tubes were quickly cut to length without the necessity of measuring each tube.

WORK THAT IS TOO LARGE FOR THE PLANER.

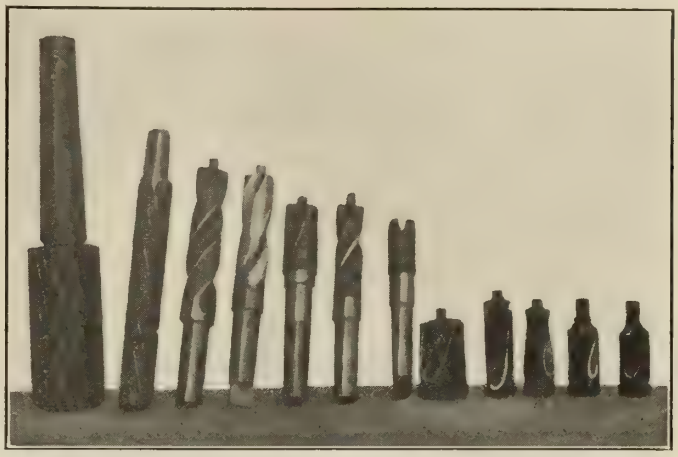
By Frederick Seabury.

The accompanying line engraving shows how a steam-hammer anvil-block that was too large to go on the planer, was machined. The block was first leveled up on the floor beside the planer, so that the top of the casting was a little below the top of the planer platen. For

Planer Adaptation

safety the casting was clamped to the floor, although its weight was such that there was no great danger of its moving under the thrust of the cut. The cross-rail with the attached head was then removed and clamped securely to a heavy angle-plate, which was bolted to the platen. A substantial diagonal brace A was then fastened to the cross-rail and platen as shown. The tool was fed, of course, by hand, and the dove-tail for the dies was planed by the use of the adjustable head in the usual manner. The job was satisfactory in every way and caused considerable comment in the shop.—Machinery.

PLANER EXTENSION.



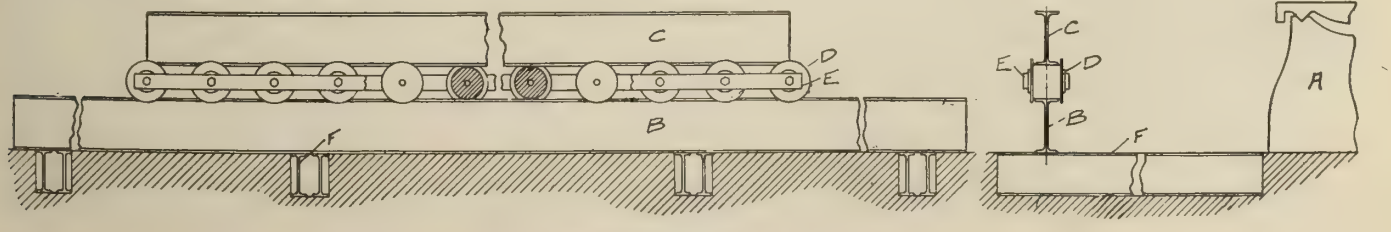
In the shops of the Collingwood Shipbuilding Co., Collingwood, Ont., there is only one planer—a side planer, with a 36-inch table. Wide articles which must be faced on the side could not be done on the planer, on account of the over-hanging part having too great tending to tip planer table. J. Smith, manager, got out the idea shown in the accompanying sketch, for increasing the capacity of the machine, so that it would take almost any size article. A is the planer, B and C two 10-inch I-beams, the former being the length of the planer bed and the latter the length of the table. Between the two beams are cast iron rollers D, held in position by side straps E. The beam B may be moved any desired distance up to ten feet away from the planer on the I-beam F imbedded in the floor, and to which the beam B is bolted.

The article to be planed is placed on the planer as desired, over-hanging onto beam C, which is slightly lower than the planer table, so that blocking is necessary. The article is bolted to this beam. The rollers are machined, but the beams are in their rough state.

HIGH SPEED STEEL DRILLS AND REAMERS.

By K. Campbell.

To make a whole drill or reamer from high speed steel is expensive, but the efficiency of the high speed steel may be obtained by making the cutting part of this steel and the shank of a less expensive steel. In the accompanying halftone are shown a number of shop tools where the cutting ends are of high speed steel. The five at the right are reamers which may be screwed on to shanks such as has been done on the next three. Thus one shank will accommodate quite a variety of sizes of high speed drills, reamers, etc.



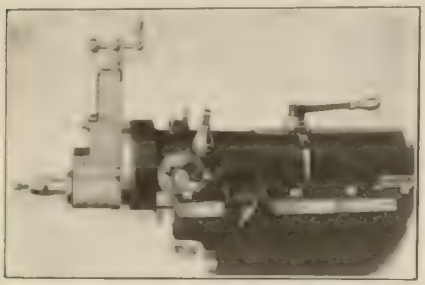
High Speed Drills and Reamers.

BUSINESS TRANSFER.

Bain & Mitchell, Y.M.C.A. Building, have transferred their business to Francis Hankin & Co., 231 Coristine Building, who have opened a machinery department, with A. G. Webster, of Bain & Mitchell, in charge. F. Hankin & Ca. will handle the agencies formerly held by Bain & Mitchell.

A really great man is known by three signs—generosity in the design, humanity in the execution, moderation in success.—Bismarck.

A grinding wheel cannot be judged by its color. Several wheels of the same grit and bond may be of different colors, owing to the material used. The conditions in the kiln will also sometimes affect the color.



Planer Extension.

DEVELOPMENTS IN MACHINERY

A Record of New and Improved Machinery Tending Towards Higher Quality and Economical Production in the Machine Shop, and Blacksmith Shop or Planing Mill.

AUTOMATIC VARIABLE FEED.

The accompanying half-tone shows the automatic variable feed to the head as applied to the Rockford shapers. It will be noted from the illustration that the

Automatic Variable Feed to Shaper Head. Rockford Machine Tool Co., Rockford, Ill.

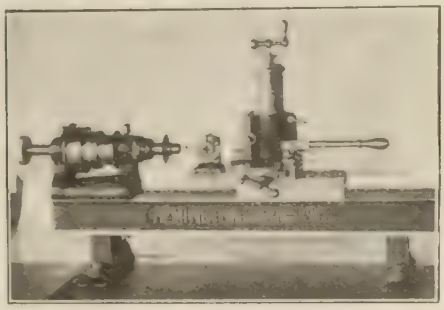
arrangement has been designed with the view of simplicity and absence of complicated parts, making it serviceable and not liable to get out of order. It feeds the tool either up or down and operates at any angle. The triangular shaped incline on which the roller rides can be readily adjusted to suit the position of ram or moved out of the way when not in use.

The lever shown on the side of ram with spring pin, regulates the amount of feed. Six changes are provided, as follows: .008, .016, .024, .032, .040, .048. The lever on top of the ram reverses the feed and throws the gears out of mesh, by placing lever in central position when not in use.

The Rockford shaper is manufactured by the Rockford Machine Tool Co., Rockford, Ill., U.S.A.

REMINGTON BENCH LATHE.

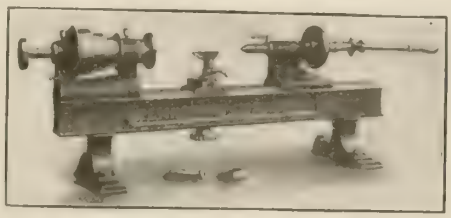
The accompanying illustrations show the bench lathe of the Remington Tool and Machine Co., Boston, Mass., which has several new attachments. The lathe



Bench Lathe with Forming and Cutting-off Slides. Remington Tool & Machine Co.

has an adjustment of two inches to increase the tension on the belts.

The spindle is of the two angle type. It takes 5-6 in. stock through the self-centering spring collet chucks, $\frac{3}{4}$" through the live spindle when a universal chuck is to be used. The end-thrust adjustment of spindle is accomplished by advancing a fibre collar to come in contact with the shoulder on the front of the spindle. This feature allows holes up to $\frac{1}{2}$" being drilled continuously without sticking or stopping of the spindle.



The tail stock is provided with combination screw feed and lever feed of the

Remington Bench Lathe.

spindle. The horizontal movement of tailstock spindles is 3 ins. The eccentric end of binder bolt has adjustment for wear.

The attachments comprise the turret with forming and cutting-off slide; milling attachment which can be used with lever as a hand milling attachment, or with ball crank handle for screw feed; and grinding attachments, inside and outside. The turret attachment has six

Precision Bench Lathe.

holes and is provided with independent stops for each tool. The forming slide has a swivel tool post graduated in degrees so that straight forming cutters may be used in turning any degree of angle.

AUTOMATIC SPRING AND AIR CHUCKS.

The Garvin Machine Company, New York, is putting on the market a very complete line of automatic chucks with two and three jaws in various sizes.

Fig. 1 shows a two-jaw chuck disassembled. The body A is of the ordinary type but carries an actuating jaw B, which has a series of inclined slots milled in it, tongues in the central draw plug C fitting into these inclined slots. By moving the plug to the rear both jaws are forced toward the center by the wedging action of the inclined slots and tongues. The dovetailed jaws are adjustable by means of a screw on the actuating jaws to and from the centre, and when adjusted are locked in place by a locking screw. The dovetailed jaw is dovetailed on both sides, so that it can be reversed and grip either external or internal work. In the latter case an extra piece C, with the diagonal slots running in the opposite direction, is necessary. The adjustment of the jaws is, therefore, entirely independent, but in operation they work simultaneously.

In detail the three-jawed are similar to the two-jawed chucks. The three-jawed chucks are furnished with the regular step type of jaws and can be fitted with various other types of jaws to accommodate all classes of work.

Fig. 1 Two Jaw Chuck Disassembled.

The chuck is screwed on the nose of the spindle in the usual manner; a pull rod or tube is then screwed into the central plug in the chuck, and the other end attached to the operating mechanism. A number of styles of operating mechanisms can be applied, governed by the conditions found in practice.

Inside the cone pulley is mounted a heavy spring, around the spindle. At the rear it bears against the spring-thrust collar through which passes a taper pin. The pin is a drive fit in the collar and also in the draw rod, but it slides, in an elongated slot, in the spindle. The spring exerts a pull of 800 pounds on the draw rod, and the wedging action of the inclined planes in the chuck multiplies this by four, giving a resultant grip, exclusive of friction, equal to 3,200 pounds on the work. A foot treadle is attached to the operating plunger at the rear end of the spindle. A slight downward pressure of the treadle carries the tube forward and automatically carries the friction out of

the cone. The momentum of the spindle is stopped by the brake pins and washer at the rear of the front box. The cone pulley is now running idle. The full movement of the treadle opens the chuck jaws, releases the finished piece of work and the chuck is ready for the reception of the next piece.

On releasing the treadle the pressure of the spring first closes the jaws on the work and then carries the friction into the cone, which starts the spindle at full speed.

Where compressed air is obtainable the system of a piston inside the cone pulley is used. Piping is attached to

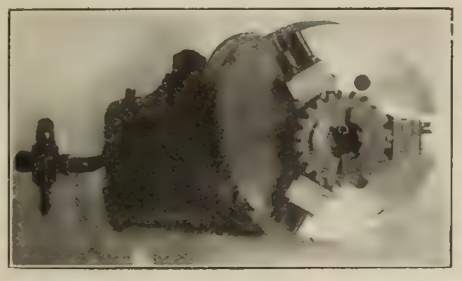


Fig. 3. Arrangement for Gripping a Spur Gear on the Pitch Line.

an air inlet at the end of the spindle, the operating valve being placed in a position convenient for the operator.

When air is turned on it passes through the chamber to the front of the piston, forcing it back and closing the chuck jaws on the work. The pressure of the air in the opposite direction carries the cone pulley on to the friction which starts the spindle forward at full speed. On releasing the air, the spring inside the spindle forces the pulley off the friction, and the momentum of the spindle is checked by a multiple-disk brake on the rear spindle bearing, which leaves the cone pulley running free. The pressure of the spring in the other direction carries the tube forward, opening the chuck jaws, and the machine is now ready to receive the next piece.

The air pressure necessary for operating is from 70 pounds up. For work which does not require a heavy grip, a reducing valve may be placed in the pipe and adjusted to give the necessary pressure.

With the air-operated chucks the jaws are at all times forced against the work by the elastic pressure of the air, and any variation in size is automatically accommodated.

These operating mechanisms are all self-contained and there is at no time while the machinery is running, any pressure on the spindle boxes.

The air system is, of course, the most powerful and convenient, because it saves physical effort, and where the number of pieces handled per day exceeds 1,000, it is the most desirable, but where there is no compressed-air system or where the number of pieces does not exceed the limit stated above, the spring actuated chuck will be found efficient.

The methods just described show applications to machines built by the Garvin Machine Co., but machines already in use can be equipped with a spring system or an air system. These mechanisms are mounted on the rear end of the spindle. They operate the chuck only, the starting and stopping being done by the countershaft. They are for this reason somewhat slower than those already shown, as the spindle is not stopped instantly.

A double air cylinder is also made, which takes the air in on either side of the piston, gripping and releasing by air pressure without the aid of a spring. This system is convenient for gripping either internal or external work, as both these can be accommodated without reversing the jaws of the chuck.

Fig. 2 shows a three-jaw air-operated chuck, arranged on a Garvin hole-grinding machine for gripping a bevel pinion by the pitch line.

Fig. 3 shows the arrangement for gripping a spur gear on the pitch line. The jaws are adjustable to and from the centre, for different-sized gears, they also carry a hardened plate on which is mounted a hardened roller which grips

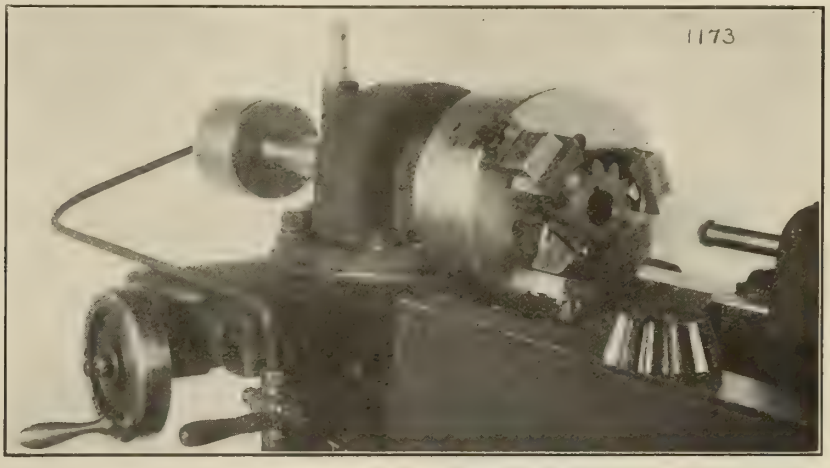

Fig. 2. Three Jaw Air Operated Clutch.

the gear at the pitch line. This plate is adjustable sideways for gripping gears where the number of teeth is not divisible by three.

These chucks may also be operated by the hand-lever mechanism. With this mechanism the chuck jaws are opened 1-16 inch on the diameter, which is sufficient for a grip on finished work. The spring or air-operated mechanisms give an increased opening and the three-jaw chucks are arranged to open $\frac{3}{8}$ inch, while the two-jaw style is made in two types, one of which opens $\frac{3}{8}$ inch and the other $\frac{3}{4}$ inch on the diameter.

The chuck shown in Fig. 4, known as the automatic index chuck, has a wide field of adaptability for that class of work having two or more points of work to be operated on lying in the same plane. These chucks are identical in construction with the former ones except that they have index jaws.

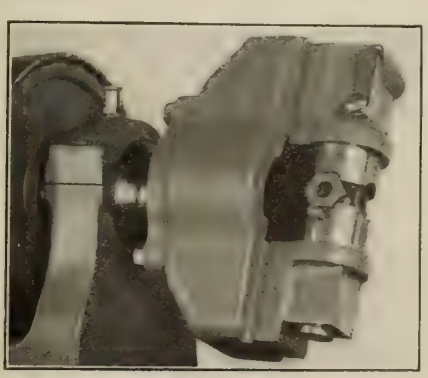

Fig. 4.—Automatic Index Chuck.

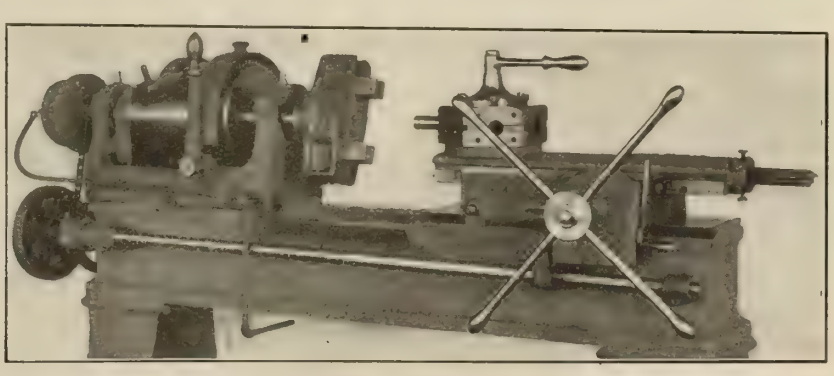

Fig. 5.—The Outside Type of Air Control.

Fig. 5 shows a Garvin geared friction-head power-feed monitor lathe, equipped with a 12-inch two-jaw adjustable reversible, automatic chuck which is operated by the outside air system. The stopping of the spindle is, in this case, done by throwing the friction lever on the headstock to a neutral position

FULL UNIVERSAL RADIAL DRILL.

The John Bertram & Sons Co., Dundas, Ont., have placed on the market a 6 ft. full universal radial drill shown in

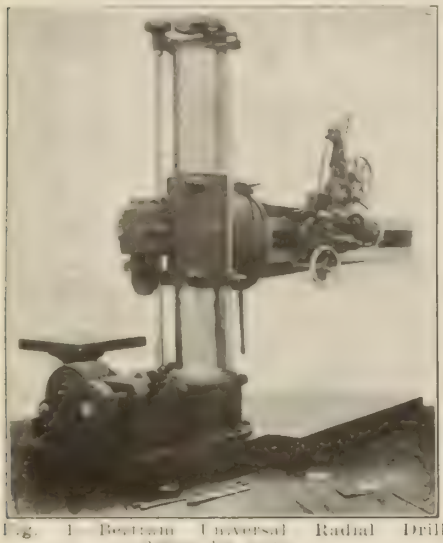

Fig. 1 Bertram Universal Radial Drill driven by motor.

the accompanying illustrations. It will drill to the centre of a 12 ft. circle. The column carrying the arm revolves on ball bearings and can be clamped in any position. The arm is raised and lowered by power. The spindle is counterbalanced and has quick return, 16 changes of speed and three changes of feed by hand or power.

The vertical travel of spindle is 17 ins.; spindle is bored to Morse taper No. 5, maximum distance spindle to

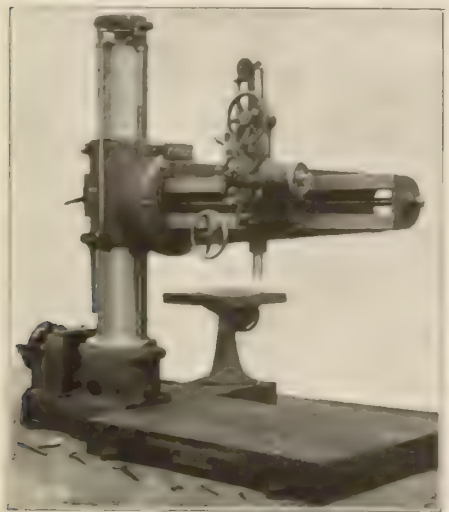

Fig. 2 Bertram Universal Radial Drill driven by single belt through speed box

baseplate is 73 ins., minimum distance spindle to baseplate, 4½ ins.; and maximum distance face of column to spindle is 72½ ins. The drill is supplied with standard work table of box section having slotted top and side. The baseplate is slotted for bolting work.

Fig. 1 shows a 6 ft. radial drill with the drive by means of a 5 h.p. constant speed motor through speed box. Fig. 2 shows a 6 ft. radial drill driven by a single pulley through speed box instead of by motor.

NEW DESIGN ROTARY PLANING MACHINE.

The diameter of cutter heads in the machine shown, over tools 26 in., length of in and out adjustment to each head by hand 2½ in., in length of cross feed to each saddle 5 ft., size of each work table 3 ft. by 6 ft., maximum distance between the faces of cutting tools 30 ft.; minimum distance between the faces of cutting tools 6 ft. 3¼ in., machine occupies a floor space of 37 ft. by 5 ft. 6 in. in the base, and the length of the cross slide for each head is 10 feet.

The cutter heads are steel castings with angular slots for the reception of tools cut from the solid with a steel band shrunk on the periphery, into which the tool retaining set screws are fitted. The internal driving face plate gear has teeth cut from the solid and the teeth of the driving pinion as well as for transmitting the feed are cut from the solid.

The drive to each head is by means of a 7½ h.p. Westinghouse Electric & Mfg. Co. type "S" motor, having a speed of 975 r.p.m. Motion is further transmitted through spiral gears to the driving worm wheel. The driving worm is of hardened steel and the driving worm wheel has a bronze ring with teeth of steep lead and both are encased for lubrication, and where necessary roller bearings are provided. The left hand machine is stationary on the base and the right hand machine is arranged to be adjusted from the minimum to the maximum distance by means of a 5 h.p. motor mounted on the back of the base, motion being transmitted from the motor through spiral gears to the worm wheel shaft, in turn meshing with the worm wheel, which controls the rack pinion. This machine is especially adapted for rapid production in finishing cast iron and structural columns on both ends.

This machine is manufactured by the Newton Machine Tool Works, Philadelphia.

FLEXIBLE HACKSAW BLADE.

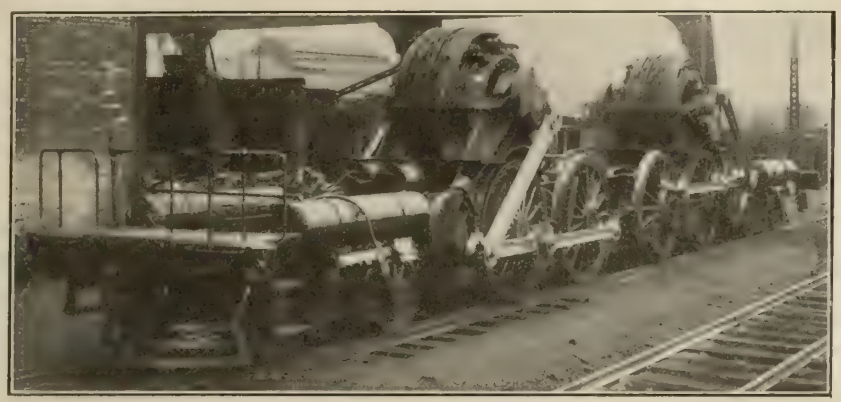
This is not an illustration of a dog collar and chain, but rather it shows the work of a Culley Flexible Hack Saw Blade, manufactured by the Simonds Mfg. Co., Fitchburg, Mass. and Montreal, P.Q. There were 47 separate

Sample of Work of the Culley Flexible Hack Saw Blades.

rings made from a 1 inch pipe, each ring slit and the chain formed. After making this number of cuts the condition of the blade was so good that the teeth are clearly defined, even in this greatly reduced illustration. The remarkable flexible property of this blade is shown by its being bent in a complete circle.

NEW LATHES OF AMERICAN TOOL WORKS CO.

The American Tool Works Co., Cincinnati, Ohio, are placing on the market a new line of 36 and 42 in. lathes, the special feature of them being the quick change mechanism, all the gears in which are steel.



The material used in the gears is made from either bar steel or drop forgings. This mechanism is embodied in a self-contained unit carried on the front of the bed and provides 32 fundamental changes of threads ranging from 1 to 14 per inch. In addition to this a com-

Special Rotary Planing Machine, Newton Machine Tool Works, Philadelphia.

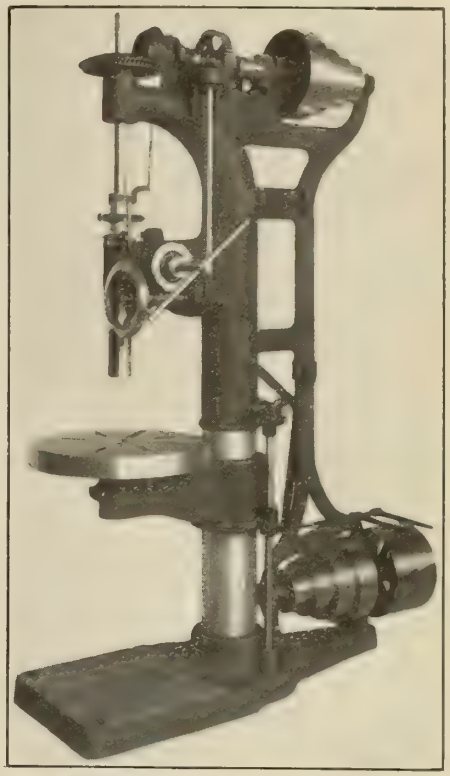
pound quadrant gear is provided on the end of bed which will furnish 16 additional changes, thus affording 48 thread and feed changes ranging from ½ to 28

threads including 11½ pipe thread and from 4 to 244 cuts per inch. The 32 changes in the box are all obtained through the medium of a cone and tumbler gear and two sliding clutches of the selective type. Anyone of these changes may be instantly obtained while the machine is running.

Electric Locomotive, Showing Motors and Running Gear.

The quadrant mentioned also provides means for obtaining through the medium of loose gears any odd rates or feeds which may from time to time be desired. The cone gears are all of the Brown & Sharpe 20 degree involute pointed type which provides an especially strong tooth and greatly facilitates the engaging of the gears while running. The coarse threads and feeds are all obtained through the cone, and no member in tne box does at any time run faster than the initial driving gear.

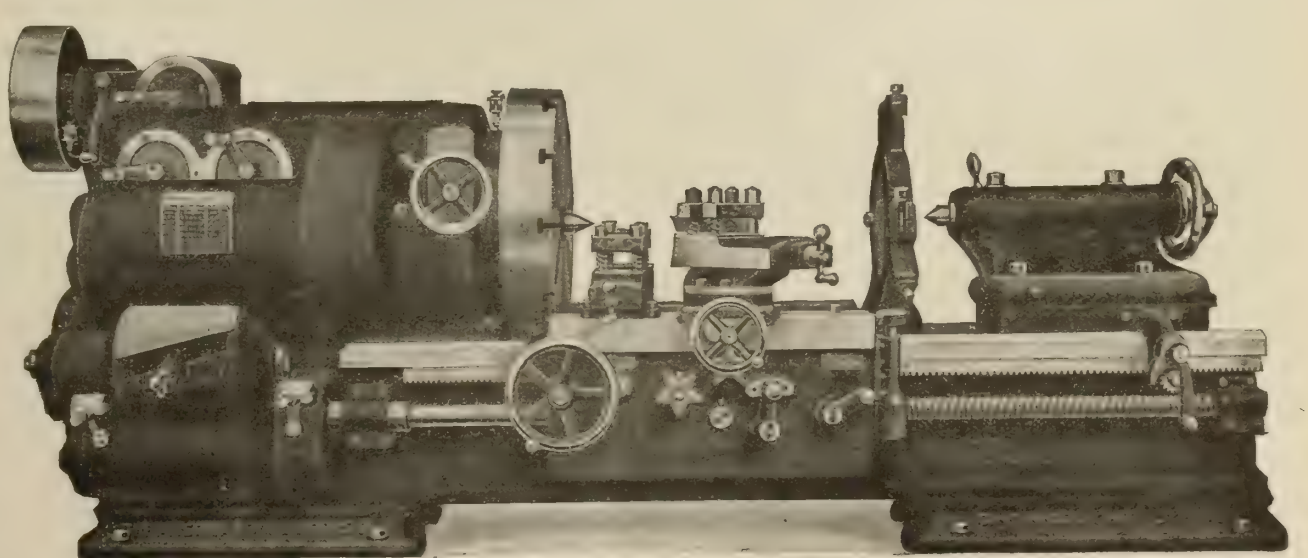
ELECTRIC LOCOMOTIVE.



In the accompanying illustration is shown the motors and running of a Westinghouse electric locomotive for D. C. 600 volts. The weight complete is 156 tons; weight on drivers, 200,000 lbs.; total length over all inside knuckles, 64 ft. 11 ins.; tractive effort 79,200 lbs., and normal speed 60 miles an hour.

The weight of the motor is 43,000 lbs., and the maximum horse power is 4,000 h.p. The locomotive is of double design, the two parts being connected at the driving wheels ends. In the event of one motor being cut out, the other motor will operate the whole locomotive and can be controlled from either cab.

NEW DRILLING MACHINE.



The solid stocky design and extreme simplicity are the distinguisning features of this new stationary head drilling machine with geared feed, the first lot of which the Sibley Machine Tool Co., South Bend, Ind., have just completed. Its rigidity and the geared feeds adapt it to the heavy cuts of modern manufacturing. While having the same range as similar models formerly made by this company it is considerably lower in height.

It will be noted that the feed mechanism derives its power from the top drive shaft, and all the gearing is completely enclosed and running in an oil bath. Four changes of feed and a neutral position are effected by moving a small knob in the centre of the hand wheel. The convenience of this arrangement is obvious.

New Drilling Machine, Sibley Machine Tool Co., South Bend, Ind.

The automatic stop collar on the spindle sleeve, trips a latch at the desired depth of hole and the worm swings away from the worm gear. Unusually severe tests have been tried with this feed, and results were so successful that the Sibley Machine Tool Co. have adopted it for their entire line, excepting the 20'' and 22½'' sizes.

36 and 42 in. Style, American High Duty Lathe.

Vol. VII. May, 1911 No. 5

DO THE HARD THINGS FIRST.

A certain manager has over his desk the motto in large letters "Do the Hard Things First." It is a motto that can be passed down to the superintendent, foreman and men. Many hard or disagreeable duties must be done and it is best to use the freshest efforts to accomplish them. The "putting off until to-morrow" in the hopes someone else will do the job is a bad policy. Attempting the hardest things first will make the day's work pleasanter and will give you a greater interest in your work.

YOUR PERSONAL EQUIPMENT.

Is [illegible] necessary and consequent improvement in the [illegible] equipment? There is another form of equipment which requires very careful examination with a similar object in view. We refer to the personal equipment—to the measure of our knowledge of the elements which constitute the ideal in manufacturing, so that the product of our own establishments shall bear some reasonable relationship to that ideal. Is our personal equipment sufficient to meet the demand with the growth of the manufacturing industry?

The mechanical equipment must ever be subservient to the personal or mental one. Even the machine shops where excellent work is being turned out, remove the men from the lathes and substitute men of but average ability, and, regardless of the efficiency of the mechanical equipment, the quality of the product will immediately drop.

We are apt to forget that the same principle applies in the case of the executive head of the establishment. Although an examination of the product of some of the leading manufacturers, would prove the correctness of the principle.

It is well to take stock as to the extent and value of our personal equipment. Will we be able to infuse into the product of our establishment a distinctive character and quality, or is our work to sink into mediocrity? Have we broadened the outlook and firm grasp upon the principles of machine shop work and management, or does our personal equipment bear the marks of wear and tear and age?

Ideas will not last for ever. They become old-fashioned, worn out and commonplace. You must be progressive, you must keep up with the present trend of practice in the shop or in its management. You must develop your personal equipment.

TECHNICAL EDUCATION FOR MECHANICS.

With evidences of largely increased agricultural, mineral and industrial development ahead, educationalists are stirring themselves to activity on behalf of those whose work lies in these particular spheres. Schemes are being propounded and preparations made, to enhance the value of labor, in commercial and industrial enterprises, by establishing technical schools in our large cities and manufacturing centres, and it is gratifying to note that the movement emanates from a substantial and reliable quarter, ensuring stability and ultimate success. The leading representatives of our great corporations foresee enough to appreciate the importance of technical education as a civilizing, vital, energizing, and inestimable asset of this or any country, and with commendable determination are seeking to transform their ideals into substantial realities.

It should be common knowledge, that the acquirement and application of technical education are unlimited in degree at least, and that individual development is necessary to its pursuit. Undue haste to be on equality of equipment with older countries is however discernible, and is to be regretted; because likely to retard real progress, and delay equal and certain successful results. A jealous, or it may be patriotic spirit due to a comparison of superior conditions in England, France, Germany and the United States, with those existent in Canada, has overcome the usually calm, calculating natures of these responsible for the movement, and will have the inevitable result in due course, of their hopes being but partly realized, and the shifting of the blame to the apathetic response of those for whom the effort was inaugurated.

Pessimistic yet true, because impossible otherwise under the circumstances, and why? The answer is, we are not ready for the equivalent equipment of the countries named, ours being comparatively speaking a new country.

The individual development already referred to as necessary is not sufficiently advanced, yea has not been more than started in this Canada of ours, and satisfactory results cannot therefore be looked for. The ground is not yet prepared, and will not be so for some years to come. The western farmer does not equip himself with the most modern and expensive agricultural implements until he has his section cleared. He does not reason indiscriminately, and expect that agricultural implements because they are named so, and were bought of a reputable maker, will overcome the neglect of clearing and ensure a bountiful harvest. Neither does a mining company, a reputable one at least, reason that it must launch into large capital outlay because rich ore has been located in the vicinity of its claim. It rather stays

its hand, however hopeful the outlook, until its own initial development uncovers wealth warranting the expenditure. For the same reason a magnificent technical institution, second to none in appearance and equipment, should not be used to get results from infinitely more difficult ground than our farmer friend contends with, or from what is in mining nomenclature a prospect whose being is justified only by what others are getting.

The old saying, "till the ground," has assuredly a weight of meaning for our technical education enthusiasts, yet it need not damp their zeal, but rather help to direct it properly and effectively. There must needs be a full realization of the condition of those sought to be served and benefited. To those already engaged in the work of technical education as applied to leading Canadian industries, it is at once apparent that knowledge of the condition of the ground material to be operated upon, does not have the prominence it should in the formulation of the promoters' plans.

It is no disparagement of students who do or may attend technical instruction classes to speak in this manner of their status. Instruction has in the past been confined to a few obscure although most effective courses in various branches. Careful individual study of each man's requirements, necessitating small classes and high fees, and an interest in his daily problems of the factory, are necessary elements in the successful prosecution of technical education.

Experience, however, goes to prove that with a plethora of ideal teaching conditions, results are not in any way commensurate with the instruction given ; proving the utter hopelessness of even approaching this low percentage efficiency in one majestic institution of congested classes. Of course this congestion will be notoriously short-lived ; for before the close of the courses, the attendance will have dwindled so much so as to call for microscopical investigation of its existence, not to speak of similar but more minute examination for results.

This is a universal experience, differing only in minute degree in countries with long established technical institutions. The actual number to really benefit is simply a skeleton of the total enrolment, and as Canada is a beginner, she should start with a modest equipment. Most of these others even with their paucity of results to-day have grown steadily from zero upwards and are still growing, in equipment too, commensurate with resultant progress. We should not presume to start at their present stage, and try to keep pace with them.

CARING FOR MACHINERY.

Any thorough system of inspection that will prevent rough usuage or neglect of machinery in the machine shop is commendable. In preventing neglect as well as in preventing accidents a pound of prevention is worth several tons of cure.

In some plants an inspector makes daily rounds inspecting carefully all elevators and elevator cables, power equipment, shafting, bearings and machine tools. The most remote corner receives as rigid an inspection as those within easy reach and the result is that the plants run without accident or breakdown for full time year after year.

The idea is a good one and may be carried still further. When certain machines are idle several months in the year they should not be allowed to rust. In too many shops this is the case. It reminds one of the farmer who leaves his mowers and binders exposed to all weather, winter and summer, and then complains because the machines wear out in a short time or do not give good service. If the idle machines are thoroughly cleaned and protected against any liability to rust, the result will be more than satisfactory.

The eternal vigilance of a trained inspector or force of responsible trained inspectors will result in removing all irregularities or any chance of neglect or accident.

BE ABLE TO SAY YES AND NO.

A certain factory manager who has made a success of his business, attributes his success largely to his ability to say "yes" and "no" and to say them at the proper time. He is a believer, as he himself, explains, in good old Saxon words. If he does not want any new factory equipment or stock, he says so without beating around the bush. On the other hand, if he thinks a thing would help him to secure greater economy in the shop or greater production without a large additional expense, he does not hesitate to accept it.

Undoubtedly there are managers, superintendents and foremen who lack the power to make up their own minds without undue delay. They temporize, lacking the courage to refuse something, which their common sense condemns, or to accept a thing which looks good, but involves new ideas and added risks. The ability to make quick decisions and make them wisely, is one of the greatest gifts assisting in making a successful manager, particularly if he has the added quality of stick-to-itiveness.

TOPICS OF THE MONTH.

An exchange of ideas will bring you excellent returns. Try it.

* * *

There should be co-operation between the mechanical and purchasing departments when ordering machine tools.

* * *

Manufacturers are beginning to realize that pure air and lots of light are factors affecting the cost of production.

* * *

Using the proper size motor for the work to be done means a saving in power and an increase in the shop efficiency.

* * *

A factory telephone system will keep foremen in their respective departments and thus keep them within reach of the men requiring their advice.

* * *

If we may judge from the number of new machine shops and additions to older plants, the machinery dealers will have a busy season during the remaining months of 1911.

* * *

The machine shop backyard scrap-pile is worth looking after. The various metals should be separated into respective piles and each pile disposed of at the proper figure. In this way the scrap pile is turned into a valuable mine.

* * *

Several managers of industrial plants, recognizing the value of Canadian Machinery, have not only renewed their subscriptions, but sent in subscriptions for a number of their employes as well. Such an expression of good will on the part of the managers, is thoroughly appreciated by the men.

POWER EQUIPMENT & APPLICATION

Expert Descriptive Articles Dealing with Selection and Purchase of Most Suitable Power Equipment for All Purposes, its Proper Application, Installation, Operation and Treatment.

GEARS AND GEARING*

By A. E. B.

Rawhide gears should be used with as coarse a pitch as possible and the breadth of the teeth should be about one-third more than cast iron gears. If the work is heavy it is well to house the teeth between flanges.

Rawhide gears are superior to fibre gears but are more or less affected by oil, water and changes in temperature. They should be kept well varnished. Fibre gears are not so affected and do not require to be varnished. The action of these gears is practically noiseless.

Forms of Teeth

Gear teeth are shaped to the form of certain curves and are known by those curves as Cycloidal and Involute.

Cycloidal teeth are formed by two curves which commence at the pitch circle and curve in opposite directions.

Involute teeth are formed by one curve and are most desirable for general practice, as greater care must be exercised with the use of Cycloidal teeth that the centre to centre distance between the gears is correct to insure a uniform velocity of the driven gear.

Involute teeth are also much stronger for the same pitch, owing to the greater thickness at the root. The teeth of a rack may be straight when used with a pinion having Involute teeth.

When driving cogs into a mortise gear they should be coated with linseed oil or thin white lead, which will enable them to be put in tighter with less danger of splitting. A coating of hot tallow and plumbago or of linseed oil and plumbago administered to the cogs after they are driven into the wheel will greatly prolong their life.

Stress on Teeth.

The stress on wheel teeth may be due either to a dead load, or a load accompanied by vibration and even with impact. In the former the maximum load being a definitely known quantity, the tooth can be proportioned as a beam loaded at one end and fixed at the other, a definite factor of safety being aimed at. In the latter, the pressure on the teeth necessary to transmit the requisite horse power may be calculated, but a much larger factor of safety should be used to cover the effects of vibration and impact. The teeth may however be proportioned by empirical rules, but in using these, care must be taken that the wheel is also calculated to be strong enough for any dead load it may have to sustain, especially when the revolutions are low per unit of time.

When metal teeth work with metal teeth and are cast simply without being afterwards cut, it is quite possible that the load may come not only on a single tooth, but on one corner of it only. With machine cut teeth the load may be considered to bear evenly along the point of the tooth and not wholly on one corner; therefore if the teeth are carefully shaped on cycloidal principles the load may be considered as divided between two teeth, especially after a short time in use.

With mortise wheels, the teeth of which are always carefully dressed and shaped and tried round in place for final adjustment, the load may be considered distributed along the tooth point and likewise divided between two teeth at least. It is always safer to reckon the load as acting at the tooth point, instead of at the pitch circle when computing the strength. Ten may be considered a desirable factor of safety for ordinary purposes; but when there is vibration and impact it should be increased in some systematic way to suit each particular circumstance.

Cast iron teeth which work into mortise wheels should be carefully filed up to gauge and not only made approximately true in shape, but have all roughness removed to minimize excessive wear of the wood cogs.

To compute the dead load at pitch circle necessary to transmit the required power as in the case of a crane, the following rule may be found useful.

Maximum load at pitch circle in lbs.

$$= \frac{\text{I.H.P.} \times 33{,}000}{\text{pitch circle velocity in ft. per min.}}$$

Power of Gearing.

Pressure on the teeth of wheels varies inversely as the number of revolutions and directly as the power transmitted. Thus for equal power transmission by two wheels running at different velocities, say 20 and 80 revolutions per minute respectively, the strain on the former will be four times that of the latter. Again, if two wheels run at the same velocity, transmitting 20 and 40 horse power respectively, the strain on that delivering the higher power will be double that of the other. Power transmitted depends largely on the number of teeth in gear at one time and also on velocity.

Proportions of Wheel Teeth.

The following proportions are commonly adopted for the teeth of wheels when cast, and are stated in terms of the pitch:

Height of tooth above pitch line...	.33
Height of tooth below pitch line....	.42
Total height of tooth	.75
Working depth of tooth	.66
Thickness of tooth	.45
Space between teeth	.55
Backlash of tooth	.10
Thickness of wheel rim and arms...	.45

To ensure durability, the width of face of teeth should be $2\frac{1}{2}$ times the pitch.

With machine cut gears a different tooth proportion is followed:

Hgt. of tooth above pitch line..	.318
Hgt. of tooth below pitch line..	.369
Total height of tooth	.687
Working depth of tooth	.637
Thickness of tooth	.48 to .5
Space between teeth	.52 to .5
Backlash of tooth	.0 to .04

A TYPOGRAPHICAL ERROR.

The Magnolia Metal Company point out an error that was made in their April advertisement by the misplacement of a decimal, which has an important bearing upon the figures shown in the table under heading of "Coefficient of Friction"—"A" WHITE BRASS—in the test by the United States Government, using water as a lubricant. The figures under this heading should read as follows:—

Magnolia No. 1	0.00159375
Magnolia No. 2	0.0049479
"A" White Brass	0.0198916
Magnolia No. 1	0.00080208
Magnolia No. 1	0.00129166
Magnolia No. 1	0.0021727
Magnolia No. 1	0.00275

"Brain power in a factory counts for more than horsepower."

We strongly suspect that the coal evolved from ashes would necessarily be "chestnut' coal.

A magnetic chuck has been found useful in holding small parts of odd shapes which had to be repaired. It grips them without the use of special vises or jaws.

Gravity circulation in heating systems, it is said, will not in the great majority of installations exceed one foot per second, and in most of them is considerably less. Also that the friction of heated water in pipes is 25 per cent. less than with cold water, the two temperatures assumed being 170 and 60 degs.

* Part II of the third article of the series of Power Transmission Equipment, Operation and Efficiency Subjects.

BABBIT METALS.

By A. A. Greenburgh.*

THERE is perhaps, at the present time, no term in the mechanical world so ambiguous and so misused as the term "Genuine Babbitt." It is popularly believed that "Genuine Babbitt" is the composition originally compounded and invented by Isaac Babbitt, to whom we are indebted for the inventon of making soft metal linings for bearings. In U.S. Patent No. 1252, July 17, 1839, granted to him, a suitable composition is mentioned, consisting of 50 parts tin, 5 parts antimony and 1 part copper. Now what his patent specifically covers and what he claims in the same, is simply the method of application of a soft lining in bearings. The formula given was for the purpose of making his specifications complete for patent office requirements. The value of his invention in his own mind related to the construction of bearings rather than to the production of an anti-frictional metal.

Later, Mr. Babbitt gave the question of the composition of his alloy some thought, and he realized that the hardest alloy consistent with other requirements was the best for him to use. The formula for his favorite composition, which some years later he sold to a Mr. Phillips, an American manufacturer, was quite different from that first mentioned in his patent, in that it contained 10 parts tin, 1 part antimony and 1 part copper. At the outset, Mr, Babbitt himself had no exact composition which he used for his linings, wherefore the term "Genuine Babbitt" cannot be used in the sense that it is Babbitt's original composition; and further it is impracticable and cannot be used as a definite specification.

Babbitt Compositions.

Still greater uncertainty is brought out by chemical analysis of the different metals sold under the trade name of "Genuine Babbitt." If the term ever meant anything at all, it was simply this : that the preponderant constituent was tin, and that its two other constituents were antimony and copper.

Until recent years the term generally implied that the composition was free from lead. This however is no longer the case, because the low cost of antimonial-lead as a by-product for the last fifteen years, and the constant increase in the price of tin have weighed so heavily on the manufacturer of "Genuine Babbitt," that to-day the term no longer positively excludes lead from its composition.

* "Babbitt' specialist, the Lumen Bearing Co., Toronto and Buffalo.

Engineers and machine builders realize that there is no such thing as one universal bearing composition that can be considered as the best and most serviceable alloy for all requirements. Bearing metal should be specified with the same degree of care and decision as any other metal used in the construction of modern machines.

Manufacturers offer alloys of widely different compositions and it is impossible to rely upon fanciful labels and brands. While apparently there should be only one "genuine," there is no reason to believe that Isaac Babbitt's formula of fifty years ago, if taken as a definitely exact composition, should apply to the completely altered bearing conditions of to-day.

There is certainly a great question as to the adaptability of any one formula to the wide range of conditions which must be provided for in these days, so that there is justification for the intelligent manufacturer in departing from any established formula; such action is due to an increased knowledge of the metals and metallurgical processes and the necessity for economical construction.

As a matter of fact, nearly all bearing metal requirements could be met with Babbitt's composition of 10 parts tin, 1 part antimony and 1 part copper. The real merit of a bearing metal lies in its giving satisfactory service at a minimum first cost

The heating of bearings is the principal cause of annoyance, and in cases where the metal punishment is so severe that heating cannot be avoided, a metal of high melting point should be selected. The efficiency of the alloy, therefore, depends upon the quality of the wearing surface that can be produced and maintained under service. A properly selected metal carefully applied, both as to design and workmanship, produces a bearing which, with proper lubrication, has no metallic contact while running. That is, the journal and its bearing are separated from each other by a film of oil which is maintained in operation. As soon as the movement of the journal is stopped, the film of oil is gradually squeezed out and the metallic surfaces are brought into contact. Therefore in selecting the metals for a bearing they should be sufficiently dissimilar so that when starting the machine, there will be no danger of scoring the shaft until the oil film shall have been restored.

Manufacturing Methods.

Manufacturing methods have a very important bearing on the serviceability of different alloys. The chemical analysis of a Babbitt, giving the constituents and their relative proportions is of course of some value in determining the quality of Babbitt under consideration; but more important still are certain fundamental, chemical and metallurgical laws according to which the constituents should be united, and if these laws have not been observed, a very inferior product will be the result. It is not the purpose here to give a metallurgical treatise but to suggest ideas that should be observed in the handling and applying of lining metals.

In general, these metals should be melted in an iron vessel and kept covered as much as possible in order to prevent excessive oxidation. They should be heated considerably above their melting point before using, but must not be kept in a molten state at a high temperature longer than necessary. Overheating should be carefully avoided, and a good rule for general practice, is to heat the molten babbitt to a point where it chars a pine stick, at which temperature it casts perfectly.

Selection of Babbitt Mixture.

The analysis of service conditions is the first important step in the selection of the most economical Babbitt for any requirement. The variable conditions of applying a bearing, as well as the care, method and nature of lubrication, all have a distinct effect upon the final results.

Where the service conditions are severe, owing to great pressure, a metal having considerable compressive strength is necessary regardless of what the speed may be, and this condition would require a relatively high percentage of tin. Where there is high speed and the pressure light and moderate, a metal having a fairly high percentage of lead may be used. In the same manner with intermediate conditions between pressure and speed, correspondingly intermediate compositions can be selected.

The surroundings of a bearing should also be taken into consideration if they are at all unusual.

Care and Attention of Bearings.

The question of care and attention that a bearing receives should also be taken into consideration. A bearing that is lubricated at long intervals or with a poor grade of lubricant requires a higher grade of metal than that which would be required under more favorable conditions.

There is nothing very difficult in making Babbitt suitable to any kind of service. It is only necessary that the work be done by an experienced metallurgist. Right here is where we see the importance and value of dealing with a maker whose experience and reputation are above question and who produces alloys of high quality and sells them honestly at fair prices.

SYSTEMATIC BUSINESS MANAGEMENT

Practical Articles for Managers, Superintendents, and Foremen, to Assist in Carrying on the Business Economically and Efficiently.

SHIPPING AND RECEIVING PLATFORM.

By M. E. D.

A great deal of time is often lost by the shipping and receiving platforms being at an inconvenient height. For instance if there is no crane in a warehouse and the platform is too low, a great deal of time is consumed in pushing materials up an incline or hoisting them in some way by manual labor.

Where a factory is already established a shipping platform can sometimes be arranged at convenient height at a low cost, but more often it will be found expensive. In erecting a new plant, however, this question should receive full consideration and the platforms arranged at the most convenient height. Not only does this question of convenient height apply to shipping and receiving by car but by team as well.

Another point is the location of the platforms. Adverse weather conditions often interfere with easy shipments and it is rather inconvenient to unload a car in the rain or in a snow storm. This is often the case in the smaller plants. The solution of this difficulty in small plants is to extend the warehouse roof over the shipping or receiving platform and this can be done at a comparatively small cost in established plants. In larger plants, depressed tracks can be laid into the warehouse, and therefore under cover, the floor of the warehouse and cars being on a level. These ideas are now incorporated in the design of a number of Canadian plants and are found to facilitate greatly the handling of materials.

RESPONSIBILITY OF MANUFACTURERS FOR TRAINING OF SKILLED MECHANICS AND SHOP FOREMEN*

By Arthur L. Williston.**

The need for an efficient way of obtaining more skilled mechanics and competent shop-foremen is everywhere apparent, said Mr. Williston. For a long time, in America, we have taken pride in the idea that we were a practical people, but we have recently been brought to realize that in several most important particulars we have been surprisingly shortsighted; we have been wasteful of forests, have exhausted the natural fertility of the soil, and have drawn upon the mineral resources of the country with little heed for the future; and now we are beginning to understand that we have been more wasteful of the undeveloped power in human beings, even than in the use of any other natural resources.

Full-time day trade schools, equipped with all the necessary tools and appliances for thoroughly practical work, and manned by efficient teachers, offer an ideal opportunity for teaching a trade and cultivating skill, intelligence, and the spirit of devotion to work. The boy's full time can be devoted to studying principles and conditions and to applying in practical ways all that he has learned. He is not at any time serving two masters, and his whole interest and energy may be concentrated in the most effective way, on these things that most help toward his greatest possible development. On the other hand, the possibility of getting any large proportion of the boys who are to enter any given trade or calling to make the necessary sacrifice of earning power in order to attend a day school, presents a very serious problem. No boy of the type of those who enter mechanical trades for a livelihood can attend a long course, no matter how great he may consider the advantages; and only those who are more persevering than the average, or who are especially favored can attend a short course. The day trade school, therefore, can best reach those of exceptional ambition who desire to become superior workmen, foremen, etc.

Data Regarding Results of Trade School Instruction.

Reliable statistics showing the exact value of the training received in a given time in each of the types of schools described are very difficult to secure and necessarily quite incomplete, but enough facts are available to demonstrate beyond a reasonable doubt that efficient trade school instruction will give an increase in earning power, both to the individual and for the employer, that could not possibly be obtained through practical experience alone.

The type of boys who enter skilled trades and mechanical occupations, by the time they arrive at an age where they can be taught trades effectively, already have an earning power which they and their families are loath to give up. As a rule it would be possible for them to do this for a year or for two years if they were absolutely convinced that the return in future advancement would be sufficient, but the evidence naturally has to be very plain and convincing. The essential thing, therefore, for the more rapid growth of the movement for the extension of industrial education is more effective methods for bringing before the boys who are about to enter industry, sufficiently convincing testimony of the value of making themselves competent in their calling in order to overcome their natural desire for an immediate change.

There is but one group of persons in the community who can effectively do this. They are the employers. I am convinced that they are responsible for a great deal of the misinformation and many of the wrong ideas that cause boys at the present time to decide questions of this kind unwisely. Their methods of rejecting applicants or of giving employment have a more far-reaching influence than many realize. I recall that, in one investigation that I made, I found that 96 p.c. of all the pupils enrolled in a very large evening class in mechanical drawing were there because a comparatively few employers had adopted the plan advising all young applicants for positions in their works to make themselves competent before they applied again, and suggesting an evening course in mechanical drawing as a means of doing so if they could not already readily read blue prints. If all employers were to carry out this policy as effectively as the small group that I have referred to, the difficulties would be largely overcome.

JIB CRANES SAVE TIME.

The value of jib cranes as time savers is being recognized in a large number of Canadian shops. It is not always possible to have the main crane to lift large castings or steel shapes on or off a machine and in many cases the jib crane has been installed.

The advantages are that it is always ready for use and convenient, the operator can quickly remove a large casting from his machine and replace it with another, without loss of time. The addition of block and tackle further facilitates the quick handling of work and increases the value of jib cranes in a shop.

* Abstract of paper presented before the Congress of Technology at the fiftieth anniversary of the granting of the charter of the Massachusetts Institute of Technology.

** Principal of Wentworth Institute, Boston, Mass.

CLEAN VS. DIRTY SHOPS.

A man's surroundings react upon his ideals, mode of thought, and ways of working. The workman who comes from a slovenly home where meals are badly cooked, the house in a litter and things generally in a disordered state, will, in the natural order of things, be a slack and unsatisfactory workman. His moral stamina will be low and his ambition listless. The best workmen, generally, are those having cheerful homes, good wives and happy children. They have something to live for and work for—ambition to some day, perhaps, hold a position of responsibility.

Granted that this is true, why should a manufacturer require his workmen to work in a dirty, ill-kept shop—where old waste and oil slip under a man's feet as he walks, and where the machines are coated with grease that never has been cleaned off since they were bought?

Cleanliness costs, and so does almost everything that is worth while; but it pays in the long run. It pays in the effect on the men, in tending to raise the standard of workmanship, in elevating moral standards, in reducing fire risk, and in saving machinery from abuse. By all means cleanliness pays, and the dirty shop is always a reproach to the management.—Machinery.

FACTORY SANITATION AND EFFICIENCY.*

By C. E. A. Winslow.**

The great economic importance of good air, or proper temperature and humidity in factories, was presented very forcefully by Professor C. E. A. Winslow, of the College of New York. Professor Winslow pointed out in the beginning of his paper the fact that humidity and temperature conditions in factories though they profoundly affect the efficiency of the workmen, have received very little attention from the manufacturer himself, and this little almost wholly under the compulsion of State laws. For the moment, said Professor Winslow, I am quite frankly and coldly treating the operative as a factor in production whose efficiency should be raised to the highest pitch, for his own sake, for that of his employer, and for the welfare of the community at large.

The intimate relation between the conditions which surround the living machine and its efficiency is matter of common experience with us all. Contrast your feelings and your effectiveness on a close, hot muggy day in August and on a cool brisk bright October morning. Many a factory operative is kept at the August level by an August atmosphere all through the winter months. He works listlessly, he half accomplishes his task, he breaks and wastes the property and the material entrusted to his care. If he works by the day the loss to the employer is direct; if he works by the piece the burden of interest on extra machinery has just as truly to be borne. At the close of the day the operative passes from an overcrowded, overheated workroom into the chill night air. His vitality lowered by the atmosphere in which he has lived, he falls a prey to minor illness, cold and grip and the disturbing effect of absences is added to inefficiency. Back of it all lurks tuberculosis, the great social and industrial disease which lays its heavy death tax upon the whole community after the industry has borne its more direct penalty of subnormal vitality and actual illness.

The remedy for all this is not simply ventilation in the ordinary sense in which we have come to understand the term. Conditioning of the air so that the human machine may work under the most favorable conditions,—this is one of the chief elements of industrial efficiency as it is of individual health and happiness.

The chief factors in air conditioning for the living machine, the factors which in most cases far outweigh all others put together, are the temperature and humidity of the air. Heat, and particularly heat combined with excessive humidity, is the one condition in air that has been proved beyond a doubt to be universally a cause of discomfort, inefficiency and disease. Flugge and his pupils in Germany and Haldane in England have shown that when the temperature rises to 80 deg. with moderate humidity or much above 70 deg. with high humidity depression, headache, dizziness and other symptoms associated with badly ventilated rooms begin to manifest themselves. At 78 deg. with saturated air Haldane found that the temperature of the body itself began to rise. The wonderful heat-regulating mechanism which enables us to adjust ourselves to our environment had broken down and an actual state of fever had set in. Overheating and excess of moisture is the very worst condition existing in the atmosphere and the very commonest.

The importance of the chemical impurities in the air has dwindled rapidly with the investigations of recent years. It was long believed that the carbon dioxide was an index of some subtle and mysterious "crowd poison" or "morbific matter." All attempts to prove the existence of such poisons have incontinently failed. Careful laboratory experiments have quite failed to demonstrate any unfavorable effects from rebreathed air if the surrounding temperature is kept at a proper level. In exhaustive experiment by Benedict and Milner (Bulletin 136, Office of Experiment Station, U. S. Department of Agriculture), 17 different subjects were kept for periods varying from three hours to thirteen days in a small chamber with a capacity of 197.6 cubic feet in which the air was changed only slowly while the temperature was kept down from outside. The amount of carbon dioxide was usually over 35 parts (or eight to nine times the normal) and during the day when the subject was active it was over 100 parts and at one time it reached 231 parts. Yet there was no perceptible injurious effect.

The main point in air conditions is then the maintenance of a low temperature and of a humidity not too excessive. For maximum efficiency the temperature should never pass 70 deg. F., and the humidity should never be above 70 per cent. of saturation. At the same time a too low humidity should also be avoided. We have little exact information upon this point, but it is a matter of common knowledge with many persons that very dry air, especially at 70 deg. or over, is excessively stimulating and produces nervousness and discomfort. It would probably be desirable to keep the relative humidity between 60 and 70 p.c.

Another point which may be emphasized in the light of current opinion is the importance of "perflation" or the flushing out of a room at intervals with vigorous drafts of fresh cool air. Where there are no air currents the hot, moist, vitiated air from the body clings round us like an "aerial blanket," as Professor Sedgwick calls it, and each of us is surrounded by a zone of concentrated discomfort. The delightful sensation of walking or riding against the wind is largely perhaps due to the dispersion of this foul envelope and it is important that a fresh blast of air should sometimes blow over the body in order to produce a similar effect. The same process will scatter the odors which have been noted as unpleasant and to some persons potentially injurious. The principal value of the carbon dioxide test to-day lies in the fact that under ordinary conditions high carbon dioxide indicates that there are no air currents changing the atmosphere about the bodies of the occupants.

There is plenty of evidence, though of a scattered and ill digested sort, that the elimination of such conditions as these brings a direct return in increased efficiency of production.

The Annual Convention of Foundrymen at Pittsburg

Plans Made for the Conventions of the Allied Foundry Associations and the Exhibit of The Foundry and Machine Exhibition Co., the Companies Exhibiting and the Equipment That Will be Shown.—It is Expected That the Attendance Will Surpass Any Previous Exhibition.

PREPARATIONS are being completed to make the Foundrymen's Convention better than any previous one. For several months the Pittsburg committees have been at work and a large attendance is assured. The allied

DR. RICHARD MOLDENKE, Watchung, N.J.
Secretary A. F. A.

foundry associations including the American Foundrymen's Association, The American Brass Founders' Association and the Associated Foundry Foremen will meet in convention, and at the same time, May 23 to June 1, the great exhibit of the Foundry and Machine Exhibition Co. will be held and the latter feature will be the most extensive in the history of the Conventions. The buildings of the Western Pennsylvania Exhibition Society, at the junction of the Allegheny, Monangahela and Ohio rivers, have been secured and over 40,000 square feet have been contracted for by manufacturers.

W. M. CORSE, Buffalo.
Secretary A. B. F. A.

The Pittsburg committee in charge of the work consists of Joseph T. Speer, president of the A.F.A., chairman; F. W. Zimmers, secretary; J. S. Seamen, chairman of finance committee; H. E. Field, chairman of convention committee; W. A. Bole, chairman of the plant visitation committee; George P. Bassett, Jr., chairman of the ladies entertainment committee; E. D. Frohman, chairman of the ball game committee; Eliot A. Kebler, chairman of the reception committee and W. B. Robinson, chairman of the press committee.

JOSEPH T. SPEER, Pittsburg,
President A. F. A.

Registration.

Registration will commence on May 22 at the Exposition Buildings when delegates or visitors are requested to follow the following instructions:

The registration committees wish to advise association members that the registration at the Pittsburgh Convention will be conducted in much the same manner as last year at Detroit.

To expedite the registration and facilitate the work at the counter, they make the following requests:

First—That each person registering will do so according to the name in which the membership stands, for instance, if John Jones is representing John Brown & Co., who are members of the A. F. A. or A. B. F. A., he will go to the alphabetical division "B," where he will present his card saying John Brown & Company are members of either or both associations, and he

N. K. B. PATCH, Toronto, Ont.
President A. B. F. A.

ROBERT B. THOMPSON, Buffalo.
President A. F. F.

will register as John Jones of John Brown & Co.

The members of the Associated Foundry Foremen will of course register individually, under the proper alphabetical division.

Second—It is also requested, when convenient that those registering will pre-

GEO. RAYNOR, Niagara Falls, N.Y.
President F. & M. Exhibition Co.

sent their business card, bearing their own name and firm name, thus making sure that the names will be recorded correctly.

With these advance hints it is hoped to make the registration an ideal one for all concerned.

A.F.A. Officers.

President, Joseph T. Speer, Pittsburg Valve, Foundry & Construction Co., Box 1016, Pittsburg, Pa.

Vice-Pres., (first district)—F. B. Farnsworth, New Haven, Conn.

HARRY D. GATES, New York.
Vice-Pres. F. & M. Exhibition Co.

Vice-Pres. (second district — Walter Wood, Philadelphia, Pa.

Vice-Pres. (third district)—W. A. Bole, E. Pittsburg, Pa.

Vice Pres. (fourth district)—William Gilbert, Cincinnati, Ohio.

Vice-Pres. (fifth district)—J. J. Wilson, Detroit, Mich.

Vice-Pres. (sixth district)—T. W. Sheriff, Milwaukee, Wis.

Vice-Pres. (seventh district)—Alfred E. Howell, Nashville, Tenn.

Vice-Pres. (eighth district)—A. N. W. Clare, Preston, Ont.

Sec.-Treas.—Richard Moldenke, Watchung, N. J.

A.F.A. Committees.

Auditing—Wm. Yagle and H. E. Field.

Metallurgy—H. E. Diller.

Papers—H. E. Field, chairman, L. L. Anthes, Ellsworth M. Taylor and A. O. Backert.

Industrial Education—P. Kreuzpointer.

A.B.F.A. Officers.

President—N. K. B. Patch, Toronto.

Secretary-treasurer—W. M. Corse, Buffalo.

T. S. HAMMOND, Harvey, Ill.
Vice-Pres. F. & M. Exhibition Co.

Vice-Presidents—Thos. Evans, Philadelphia; J. C. Sharpe, Chattanooga; W. L. Abate, New York; W. H. Carpenter, Bistol; Richard Augenbraun, Standford; L. M. Olson, Mansfield; John Wollf, Chicago; J. N. Gamble, Kewanee, Ill.; and Richard R. Mitchell, Montreal.

Convention Programme.

On Tuesday, May 23, a joint session of the associations will be held when papers will be read on "Production Cost," "Economic Foundry Insurance" and "Uniform Contracts." In the afternoon separate sessions will be held and in the evening the exposition will be open for delegates.

On the evening of May 24 will be the dinner of the Pittsburg and Associated Foundry Foremen. On the afternoon of May 25 will be the ball game between the Pittsburg and Cincinnati clubs of the National League.

WILFRED LEWIS, Philadelphia.
Vice-Pres. F. & M. Exhibition Co.

Besides the many special features of the program there will be the added attraction of visiting Pittsburg foundries, complete arrangements having been made for the visitors to inspect them.

Papers to be Read.

The following papers will be read before the A. F. A.:

"Economical Insurance for Foundry Properties," by S. G. Walker, Providence, R.I.
"Foundry Construction," by Geo. K. Hooper, New York City.
"Vanadium Iron and Steel Castings," by G. L. Norris, Pittsburg.

C. E. HOYT, Chicago.
Secretary F. & M. Exhibition Co.

"The Foundry at Close Range," by Benj D Fuller Cleveland

"The Permanent Mold," by Edgar A Custer Philadelphia

"Titanium in Iron and Steel Castings," by Chas V Slocum Pittsburg

"Production Costs," by Ellsworth M Taylor New York City

"The Manufacture and Annealing of Converter Steel Castings," by Bradley Stoughton, New York City

"The Electric Steel Furnace for Steel Castings," by Dr P Heroult New York City

"Titanium in Malleable" by C H Gale Pittsburg.

"The Practicability of the Induction Furnace for the Making of Steel Castings," by C H Vom Ruu, New York City

"The Rotary Blower for Cupola Use," by R H Roe Schenectady N.Y.

"Open-Hearth Steel Foundry Practice," by R A Bull, Granite City, Ill

"Pattern Shop Apprentice," by Jabez Nall, Cleveland.

"The Application of Lifting Magnets to Foundry Work," by A C Eastwood, Cleveland

"Electric Motor Drive for Foundries," by Brent Wiley Pittsburg

"The Steel Open Hearth Furnace for Steel Castings" by Walter MacGregor, Chicago.

"Microscopic Structure of Iron and Steel," by Prof Wm Campbell, New York City.

"Manganese and Silicon in the Foundry," by A E. Outerbridge, Jr., Philadelphia.

"Gas Cavities Shot and Chilled Iron in Iron Castings," by Thos. D. West, Cleveland.

"Coremaking and Core Machines," by Arch. M Landon, Elmira, N.Y.

"Molding Machine Practice," by E. H. Mumford, New York City.

"Machine versus Hand Molding," by John Alexander, Philadelphia.

"Defective Castings and How to Handle Them," by John M Perkins, Detroit.

"Core Room Practice," by F. A. Coleman, Cleveland.

"Cupola Melting Practice," by P. Munnoch, New York City.

"Malleable Castings," by W. P. Putman, Detroit.

"The Equipment of Air Furnace Using Oil as Fuel," by N. W. Best, New York City.

"Instruction Paper on Phosphorus in Cast Iron," by R. E Field, Pittsburg.

"Mechanical Charging of Cupolas," by G. R Brandon, Harvey, Ill.

"Pattern Equipment," by W. S. Giele, Philadelphia.

"Recovery of Foundry Waste," by S. A. Capron Westfield, Mass.

"Cupola Practice," by R. H. Palmer, Salem, O.

"The Foundry Foremen's Educational Movement," by D. O. Wilson, Newark, N.J.

"The Briquetting of Metal Borings and Turnings," by Dr. R. Moldenke, Watchung, N.J

Presentation of data on the molding sand tests of the American Foundrymen's Association.

Memorandum on the standard test for cast iron.

• • •

The following is a partial list of papers to be read before the A B F A.:

"Alloys," by Dr W. R. Whitney.

"Corrosion of Brass Foundry Products," by Wm Vaughn of A. D. Little, Inc.

"The Pouring and Melting Points of some High Grade Bronzes," by C P. Karr.

"Annealing and its Non-Ferrous Alloys," by W C Lane.

"The Pyrometer and the Aluminum Foundry" by H W Gillett

"Non Ferrous Foundry Economics Refinements" by E A Barnes

"Determination of Nickel in Alloys," by S. W Parr.

"Equilibrium Diagram," by H W Gillett

A.S.M.E. Meeting.

A feature of interest at the meeting of the American Society of Mechanical Engineers during the second week of the Exhibit. Engineers attending the A S M E meetings, therefore, will have an opportunity of inspecting the exhibits and exhibitors will have an opportunity of attending the A S M E meetings

Exhibitors and Exhibits.

Some conception of the exhibit may be obtained from the following list of exhibitors and the equipment that each company will show. This list is only partial as replies were not received in time for publication, from a large number of other manufacturers who will be represented.

Exhibitors and Their Exhibits.

The Adams Co., Dubuque, Iowa.—Various sizes of Farwell squeezers, a few of the 72 styles of molding machines. Demonstrations will be made of the squeezers with a variety of patterns.

J. B. Wise, Watertown, N.Y.—One each of Nos. 150, 250, and 440 M.R.V. furnace.

Sand Mixing Machine Co., N.Y.—Auto Sand Mixer, a self propelled machine for cutting molding sand and for mixing core sands and facing sands. Representatives: William A. Heartt, Hutton H. Haley, John Bradley, B. F. Doup and V. E. Minich.

Herman Pneumatic Machine Co., Zelienople, Pa.—Four Herman jarring molding machines: One 24x30 inch. Herman jarr ram stripping plate machine, wherein the mold is rammed by the jarring process and the pattern drawn by same machine for the use of side lifting cylinders that engage the stripping plate and strip the mold off the pattern; two 30x45 in. Herman jarring molding machines, equipped with rollover and pattern drawing device, made especially for the purpose of making lavatories; and one 60x60 inch. Herman jarring molding machine, to be used for jarring purposes only, (commonly called bumper). This machine will simply ram the mold and be rolled over by the use of a crane and the pattern drawn by hand in the usual manner. An overhead tramway and trolley will be exhibited. Representatives: A. M. Frauenheim, M. L. Heyl, Charles Herman, Alfred Herman, Andrew Rodgers and C. E. Pettee.

Arcade Mfg. Co., Freeport, Ill. — Arcade molding machines in operation; Norcross jarring machine, 3-cylinder type; Norcross jarring machine, single cylinder type; Norcross core jolt machine; modern molding machine in three types; Arcade rotary sand sifters; Arcade squeezer; perfect match plate hinge; modern automatic power molding machine, with sand elevator and dropper. Representatives: E. H. Morgan, Chas. Morgan, L. L. Munn, F. N. Perkins, R. M. Burton, W. C. Norcross.

Goldschmidt Thermit Co., New York.—Will show full line of metals produced free from carbon, including: Chromium 97-98 per cent., manganese 97-98 per cent., ferro titanium 20-25 per cent. Ti., ferro vanadium 30-35 per cent. V., manganese titanium 30-35 per cent. Ti., manganese copper 30-70 per cent., manganese tin 50-50 per cent., manganese zinc 20-80 per cent., ferro molybdenum 80 per cent. molybdenum, ferro boren 20-25 per cent. boron. In addition to these metals will be shown heating Thermit cans for reviving dull iron in the ladle, making semi-steel, keeping risers of castings liquid and preventing piping in steel ingots; Titanium Thermit cans for purifying molten iron and increasing its fluidity and enabling the production of castings of higher quality and greater density. Demonstrations will be given showing the value of the Thermit process for welding and repairing castings and forgings, and a number of specimen welds will be on exhibition. A complete line of welding appliances will also be shown with photographs of important repairs. Representatives: William C. Cuntz, E. A. Beck, H. S. Mann and William R. Hulbert.

Tabor Mfg. Co., Philadelphia—Plain power squeezers, power squeezing split pattern machines, hand roll-over machines, power roll-over machines, shockless jarring machine, combined shockless jarring and roll-over machines, jarring, squeezing roll-over machines, Taylor-Newbold saws, Taylor-Newbold milling cutters and Taylor Universal tool grinder. The molding machine portion will be in operation. Representatives: Wilfred Lewis, H. W. Brown, John T. Ramsden, C. W. Coleman, J. H. Coleman, C. H. Ellis and Glen B. Hastings, John Pfender Dudley, Willcox, H. W. Impey and D. J. Martin.

William Sellers & Co., Philadelphia—Centrifugal belt driven sand mixing machine, centrifugal motor driven sand mixing machine, motor driven drill grinding machine, motor driven universal tool grinding and shaping machine.

Ingersoll-Rand Co., New York—Air compressors, pneumatic chipping hammers, sand hammers for bench and floor work, riveting hammers, piston and rotary drills, motor hoists and stationary motors. Representatives: W. H. Armstrong, W. A. Armstrong, E. P. Mooney, W. B. Brendlinger, H. E. Metcalfe and J. S. Kelly.

Gardner Machine Co., Beloit, Wis.—A double-head patternmaker's disc grinder in operation, a No. 14 combination metal grinder, a No. 2 special equipped disc grinder, a No. 6 machine with ring wheel chucks and cup wheels and a No. 11 Band polishing machine.

National Core Oil Co., Buffalo—Various oils manufactured and cores made from them. Representatives: C. H. Cotton, P. L. Crandall, C. M. Anderson, J. J. McCarty and B. J. Cummins.

International Molding Machine Co., Chicago Small and large stripping plate machines, turn-over draw machines, core-making machines and squeezers. Representatives: Edward A. Pridmore, W. W. Miller and J. W. Dopp.

Lawlor Improved Jarring Molding Machine Co., Pittsburg—There will be shown a 54x64 in. Lawlor improved jarring machine, bumper, and a portable combined jarring and squeezing machine, with 13x38 in. table plate for a 37-in. radiator pattern.

Jonathan Bartley Crucible Co., Trenton, N. J.—Different sizes of crucibles, including special crucibles, retorts, phosphorizers, stoppers, etc. Representatives: Samuel H. Dougherty, Lee T. Ward, Herbert D. Cole and Lewis H. Lawton.

Morner & Smith, Dayton, Ohio—Aluminum snap flasks. Representatives: Louis Morner and Chas. D. Smith.

Detroit Core Machine Co., Detroit—Detroit core machines, which are foot-power, jar-ramming, roll-over machines, adapted to small and medium-sized irregular cores.

Hawley Down Draft Furnace Co., Chicago—Will have on exhibit a miniature iron foundry.

Chicago Pneumatic Tool Co., Chicago—Pneumatic sand rammers and sifters, chipping hammers, a pneumatic hoist and electric grinder. Air will be furnished by a Franklin compound belt-driven air compressor.

Brown Specialty Machinery Co., Chicago—Standard hammer core machine and style "C" hammer core machine, with cutting-off and tapering machines. Representatives:—Elmer A. Rich, Jr., and John Laycock.

Joseph Dixon Crucible Co., Jersey City—Crucibles and graphite products. Representatives: Dudley A. Johnson, F. R. Brandon, John A. Condit and Frank Krug.

Albany Sand & Supply Co., Albany, N.Y.—Booth will be arranged as rest room and office.

S. Obermayer Co., Cincinnati, Ohio—Rest room with catalogues, in charge of E. D. Frohman.

Gardner Printing Co., Cleveland.

Oliver Machinery Co., Grand Rapids, Mich.—Will exhibit a complete line of pattern-making and flask-making machinery in operation, and will consist of No. 60 Universal saw bench, No. 90 Universal saw bench, No. 16 band saw, No. 17 band saw, No. 12A hand jointer, No. 14B hand jointer, No. 144C hand jointer, No. 61A surface planer, No. 99B surface planer, No. 24R wood lathe, No. 19F speed lathe, No. 128 patternmakers' bench, No. 481 Universal tool grinder, No. 482 Universal tool grinder, No. 53B speed lathe, No. 55B speed lathe, No. 56A speed lathe, No. 41A disc sander, No. 30 vertical spindle and disc sander, No. 72A vertical spindle borer, No. 0 wood trimmer, No. 7 wood trimmer, No. 3 wood trimmer, No. 9A wood trimmer. A special exhibit will be made of No. 102 new style Oliver Universal wood milling machine for making irregular shapes. Representatives: Joseph W. Oliver, A. N. Spencer, Geo. F. Reinhard, A. S. Kurkjian, Walter Mentzer, Arthur Blake and R. A. Smith.

Canadian Foundryman, Toronto—Represented by H. V. Tyrrell and Peter Bain.

Berkshire Mfg. Co., Cleveland, Ohio—Hand squeezing and pattern drawing molding machine, plain squeezers and automatic molding machines, also a full line of snap flasks, iron flasks, etc. Representatives: R. H. York, J. N. Battenfeld, C. F. Battenfeld, salesman and demonstrators.

Metal Industry, New York.

Standard Linseed Co., Cincinnati, Ohio—Standard foundry linseed oil for core-making purposes.

Superior Sand Co., Cleveland, Ohio—Samples of all grades of molding sand for the production of heavy machinery, car wheels, ingot molds, heavy malleable, medium and light malleable and grey iron, brass and aluminum castings, including No. 5 Rodgers molding sand for production of grey iron, malleable or semi-steel. Representatives: W. H. Smith and H. C. Krontz.

Henry E. Pridmore, Chicago—Stripping plate machines, rock-over drop machines and their new electric motor-driven jarring mach-

ine. Representatives: R. E. Turnbull, D. F. Eagan, A. V. Magnuson and Henry A. Pridmore.

Burrows Adding Machine Co., Detroit—Cost machine will be shown which is arranged to print and add simultaneously workman's number, number of hours' work and wage due. Eight or ten different machines will be on exhibit and the booth will be in charge of Ward Ganete and H. F. Happer.

Shepard Electric Crane & Hoist Co., Montour Falls, N.Y.—One traveling crane trolley, one travelling crane cage complete with controllers, one back-geared electric motor, and one caged controlled electric monorail hoist.

Hauck Mfg. Co., New York—Will exhibit a complete line of oil burning appliances, particularly of portable type, including cupola lighters, ladle heaters, core oven and furnace burners, mold driers, pre-heating and brazing outfits, all of which will be shown in operation. Representatives: A. E. Hauck, A. P. Link, A. H. Stein and H. E. Giersch.

Sterling Wheelbarrow Co., West Allis, Wis.—Foundry flasks.

Buckeye Products Co., Cincinnati.—Exhibit will cover their complete line of supplies. They will demonstrate their special products such as Buckeye parting, brass flux, Linco core compound, Buckeye binder and blacking. Representatives: Charles J. Goehringer, Edward Leisl and travelling representatives.

A. Buch's Sons Co., Elizabethtown.—Three combination jar and squeezer molding machines; patented aluminum snap flasks, square and tapered; patented steel flask bars; Buch's pattern cement; bottom boards; cast iron casings, cast iron flasks for gravity machine with bottom boards and bars; special pouring ladle; patterns, castings, etc. Representatives: R. S. Buch and Geo. E. Bates.

T. J. Peterson Co., Chicago—Cores made from Peterson Company's oils in different foundries. Five demonstrators will show the use of oil in sand for making cores.

J. W. Paxsom Co., Philadelphia—Will have a full line of photographs, blue prints, catalogues, etc. A number of representatives will be present.

J. S. McCormick Ca., Pittsburg, Pa.—Two McCormick continuous sand mixers with screens, one Perfection electro-magnetic separator and general foundry facings and supplies. Representatives: J. S. McCormick, T. E. Malone, S. R. Costley and R. H. Mills.

Tate, Jones & Co., Pittsburg—Stationary brass melting furnaces; No. 0 pumping, heating and regulating system; oil burners for mold drying, cupola lighting and ladle drying.

E. Killing's Molding Machine Works, Davenport, Iowa.—Stripping plate machine, rollover machine, multiple cylinder plain jarring machine, jarring rollover (two sizes) machine and automatic squeezer. Representatives: E. Killing, A. W. Fox, C. P. Axbye and Geo. Heck.

Carborundum Co., Niagara Falls, N.Y.—Carborundum and Aloxite grinding wheels, Carborundum fire sand and rubbing bricks. Wheels will be shown under actual working conditions. Representatives: Geo. R. Rayner, W. W. Sanderson, O. C. Dobson, Anthony Dobson, J. P. McCann, C. D. Sargent, and H. A. Eaton.

Standard Sand Machine Co., Cleveland.—One of their latest improved batch mixers with side drop clean out doors and revolving screen, No. 1 rolling and sand blending machine; and a No. 4 proportioning, screening, mixing, rolling and bonding plant for steel foundries, weight over 11 tons.

Penton Publishing Co., Cleveland.

W. W. Sly Mfg. Co., Cleveland, Ohio—A miniature set-up of cleaning mills, cinder mill and dust arrester in running order, and also sand blast machinery. Representatives: W. W. Sly, W. C. Sly, G. J. Fanner, H. J. Norris and H. R. Morse.

Detroit Foundry Supply Co., Detroit, Mich.—Booth will be fitted as a rest room. Representatives: H. Bruce Howard and M. Z. Fox.

Detroit Hoist & Machine Co., Detroit—Pneumatic geared hoists, pneumatic motors and pneumatic winches.

Hanna Engineering Works, Chicago—Rathbone multiple molding machine, Hanna pneumatic shakers, revolving pumping riddle, mold dryer, Hanna riddle oscillator, riveter, vibrators, blow guns, etc.

Pickands, Brown & Co., Chicago—Exhibit will consist of a display of Solvay coke arranged to show a portion of a bungalow or cottage. Representatives: B. T. Bacon, E. A. Bateman, C. N. Turner, G. A. T. Long and J. A. Galligan.

Mumford Molding Machine Co., Plainfield, N. J.—Split pattern power ramming machine with vibrator, plain squeezer with match plate roll-over mechanism, 10-in. high trunnion squeezer with match plate and vibrator, 10-in. plain jolt ramming machine with new style valve, 3-in. plain jolt ramming machine also with new style valve and sections of this machine showing in full detail this new valve arrangement.

The Cleveland Pneumatic Tool Co., Cleveland, O.—A line of sand rammers, riveting and chipping hammers, air drills, all sizes, emery grinders, Bowes air rose couplings, etc. The various tools will be shown in operation. Representatives: H. S. Covey, sales manager; Arthur Scott, superintendent, and J. T. Graves, salesman.

The Osborn Manufacturing Co., Cleveland, O.—Plain jolt molding machines, no-lift core jarring machines, roll-over rock-down molding machines, direct draw roll-over molding machines, rock-over molding machines, flask stripping machines, stripping plate machines, drop plate squeezing machines, mechanical pattern drawing device. The latter apparatus is for drawing patterns of large size from molds placed on the floor, and is a portable machine adapted to use on various sizes of flasks with patterns of from 6 to 15 inches depth.

The following companies will also exhibit: American Vandium Co., Pittsburg; Birkenstein & Sons, Chicago; Elmira Foundry Co., Elmira, N.Y.; Harbison-Walker Refractories Co., Pittsburg; Hill & Griffith, Cincinnati; Interstate Sand Co., Zanesville; Lupton's Sons Co., Philadelphia; Ohio Sand Co., Conneant; Osborn Mfg. Co., Cleveland; Robinson Auto Machine Co., Detroit; Rockwell Furnace Co., New York; Ross-Tacony Crucible Co., Philadelphia; Frederic B. Stevens, Detroit; U. S. Graphite Co., Saginaw; Wadsworth Core Machine & Equipment Co., Cayahoga Falls; Whiting Foundry Equipment Co., Harvey, and Williams-Davis Co., New York.

TRADE GOSSIP.

The Galt Brass Co., Galt, are enlarging their plant.

George White & Sons, London, recently completed a new foundry at a cost of $20,000.

R. McDougall, Galt, have let the contract to Wm. Edmonds for a new molding shop.

The Anthes Foundry Co., Toronto, have purchased a site in Winnipeg, and will erect a foundry.

It is stated that the Atikokan Iron Co., Port Arthur, intend erecting a foundry for the manufacture of pipe.

Edward Gurney, president of the Gurney Foundry Co., Toronto, is touring Europe. He will be absent about six months.

The Canadian Westinghouse Co., Hamilton, are planning to double the capacity of their foundry. Additional cupolas and core ovens will be installed.

S. Twist, until recently associated with the Gurney Foundry Co., Toronto, is now mechanical superintendent of the foundry of the Dominion Stove and Foundry Co., Penetang, Ont.

Reginald Redden, who has been employed for some time with the Lloyd Foundry Co., Kentville, N.S., has taken a position with the Scotia Foundry Co., Halifax.

The Welland Machine and Foundries Ltd., have been awarded the contract to supply 150 tons of gray iron castings for the construction of the Page-Hersey Works.

The Ontario Gazette contains notice of the increase in the capital stock of the National Iron Works, from $200,000 to $1,000,000, by the issue of eight thousand shares of new stock of $100 each.

Somerville Ltd., and the General Brass Mfg. Co., Toronto, have merged their interests under the title United Brass & Lead Co., with a capital of $500,000. The promoters are: Alex. F. Fuller, Chatham; Fred Somerville, Toronto; Murray James, Woodbridge; Lorne M. Somerville and Andrew J. Somerville, Toronto.

Edward A. Pridmore, W. W. Miller and D. C. Snow, of Chicago, designers and manufacturers of the "International" molding machines, and who have been doing business temporarily under the name of the Edward A. Pridmore Co., have adopted the International Molding Machine Co. as their permanent name. J. W. Dopp, who is well known among the foundry trade in the Central States, having been western sales manager for the Tabor Mfg. Co., about six years, has been appointed general sales manager by the International Molding Machine Co. Previous to his connectian with the Tabor Mfg. Co., Mr. Dopp had charge of the molding machine departments of several of the largest foundries in the country, among them being the Cambridge, Mass. plant of the International Steam Pump Co.

On April 27th the workshops of the Canada Car and Foundry Company were the scene of the most disastrous fire that has visited Amherst for years. The origin of the fire is a mystery. The flames spread from the forge shop to the grey iron foundry, to the machine shop, to the blacksmith shop, to the brass foundry and to the store rooms of the bolt and forge departments. All these buildings were soon a mass of flames, and nothing remains of them but blackened walls and twisted iron rods and wheels. The two erecting shops, the axle and wheel shops, rolling mills and malleable iron works and original wood-working plant of the old Rhodes-Curry Company were not touched by the flames. In fact fullv seven-eighths of the plant escaped damage. The loss will be in the vicinity of one hundred and fifty to two hundred thousand dollars. Insurance will be divided between practically all the companies doing business in Nova Scotia. As work in the diflerent shops is dependent upon the output of the other departments, it is probable that fully eight hundred men will be temporarily thrown out of employment.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Foundry and Machine Shop.

PALMERSTON, ONT.—The McIntyre Automobile Co., the Canadian branch of the well-known McIntyre Co., of Indiana, propose establishing a plant here. They will probably install $25,000 worth of machinery.

WELLAND, ONT.—An order for one thousand steel cars has been received by the Canada Car & Foundry Co. The cars are to be built by the C.P.R. The Canada Car & Foundry Co. have plants at Welland and Montreal. Part of the cars will be made at Welland and the remainder at the latter city.

CLINTON, ONT.—It has been reported that a large American auto firm will take over the Thresher Co.'s plant here and establish a branch automobile industry.

GALT, ONT.—The Canada Potato Machinery Co. have taken over the business of A. M. Rush, of Preston, manufacturers of stable supplies, and will move it to this city.

SYDNEY, C.B.—At the annual meeting of the Marine & General Engineering Co., held recently, it was announced that a Norwegian chain making concern is anxious to locate here. If the negotiations go through successfully Sydney will have the only chain-making industry in Canada.

ST. CATHARINES, ONT.—The City of St. Catharines has granted to Steel & Radiation, Ltd., 30 acres of land. An extensive plant, comprising six large buildings, will be erected thereon. The buildings will be all brick, surfaced with concrete. The first to be erected, work on which has been commenced, will be the foundry, which will cover a ground space 120 by 200 feet. Other structures will include machine and pattern shops, and the plant, when ready for occupancy, will cost approximately $125,000. Mr. Herbert has let the whole work to F. C. Hitch & Co., Montreal, and construction is being done under day work supervision.

SARNIA, ONT.—The Peterson Foundry property has been leased to the Acheson Graphic Co. for a year.

GALT, ONT.—The Galt Brass Co. are adding a storeroom to their plant and installing additional machinery.

MARYFIELD, SASK.—Humphries & Bennett have taken over the business of S. A. Anderson & Co., boiler makers, machinists, etc.

WESTPORT, ONT.—A disastrous fire wiped out the Electrical Plate Works, better known as the Westport Foundry Co., here, recently. The loss will not be covered by insurance, only a few tools being saved.

FORT FRANCES, ONT.—It is current report that the C. N. R. have prepared plans whereby they will establish their car shops at Fort Frances.

ST. CATHARINES, ONT.—The Yale-Towne Co., of Stamford, Conn., will establish a big lock manufacturing plant here, and give employment to 200 people.

VANCOUVER, B.C.—The new shipbuilding plant for J. R. VanDyke & Son, formerly of Everett, Wash., is completed and in operation.

HAILELBURY AND OTTAWA, ONT.—T. A. Magee, machines, has assigned to W. A. Cole.

GALT, ONT.—Reports from the Canadian Motors, Ltd., opened a few months ago, are very encouraging, especially since the Montreal motor show, where they secured a large number of orders. Their representative is now out west in quest of business.

NEW WESTMINSTER, B.C.—The Schaake Machine Works have been working overtime of late in an endeavor to clean up the order list. A large quantity of mill machinery has been manufactured lately.

VANCOUVER, B.C.—The Call Automatic Switch Co., of Denver, Colorado, which has a capital of ten million dollars, have decided to organize a Canadian company to manufacture railroad switches, and more particularly the Call automatic switch. They expect to build a factory in Vancouver, having a capacity of 50 switches per day, and employ about 200 hands. The demand for railroad switches in Canada at the present time far exceeds the home supply, and there seems to be a great opening for a business of this kind, especially in western Canada. In three years' time the stock of this concern has risen from 10 cents to $10 per share.

HALIFAX, N.S.—The Canada Iron Corporation are extending their steel plant at Londonderry, and hope to be running full blast by midsummer.

TORONTO, ONT.—The crane foundry of J. Hepburn was damaged by fire to the extent of $6,000 some time ago. A large number of valuable patterns were destroyed.

CARLETON PLACE, ONT.—The car wheel works here have been taken over by an American syndicate. They are said to have a contract of 200 wheels per day for five years.

PETERBORO, ONT.—Fire caused $300 damage to the Lundy Tool & Shovel Co. here recently.

CALGARY, ALTA.—It is said that Sir Thos. Shaughnessy will come here next autumn and look over the situation before any definite steps are taken to establish the C. P. R. shops here.

The Cushman Chuck Co.
Hartford, Conn., U.S.A.
Established 1862

GALT, ONT.—The R. McDougall Co. are adding a new molding shop to their plant here. It will be of brick and steel.

WINDSOR, ONT.—The Walkerville plant of the Dominion Motors Co., which recently went into voluntary liquidation, is again in operation, under new management. The assets of the company have been acquired by Enoch Smith, Detroit, who represents a group of Detroit and Windsor capitalists.

TORONTO, ONT.—The Polson Iron Works are building a huge floating dock here, to consist of two sections or pontoons, with high sides and open ends, each section being 150 feet at the side and 165 feet over the outriggers. Each will have a lifting capacity of 2,250 tons, and have two electrically-driven centrifugal pumps, with a capacity of 5,000 gallons per minute.

WEST TORONTO, ONT.—The C. P. R. are adding a bridge-building shop to their premises here.

PORT MANN, B.C.—The American Car & Foundry Co., of Pittsburg, Pa., will establish a huge plant here. It will be operated under the title of the British Columbia Steel Corporation. They will manufacture freight cars at the start, but will eventually build the latest models of Pullman and other passenger coaches. The capacity will be one thousand tons daily. There will be two 300-ton blast furnaces and five open-hearth furnaces, together with all other incidental equipment required to turn out the highest grade of steel.

MONTREAL, QUE.—The Dominion Steel Co. has a contract from the G. T. R. for 40,000 tons of steel rails. Fifteen thousand tons of this order will be delivered in November and December. The cost will amount to considerably over one million dollars.

HINTONBURG, ONT.—The C. P. R. are erecting a semi-circular sixteen-stall roundhouse here.

FORT WILLIAM, ONT.—The Imperial Oil Co. are making extensive improvements to their plant here, including an addition to the storage capacity of 1,500,000 gallons; a new coal handling plant on the island to cost $3,000,000 and a new cleaning elevator.

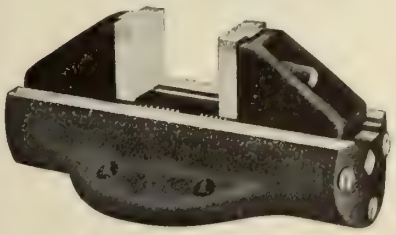
LETHBRIDGE, ALTA. — The Canadian General Supply Co., a wholesale distributing company, have located here. They will handle a complete line of mine, mill, building and contracting supplies, and also deal in the following main specialties: Gasoline locomotives, for mine hauling purposes, manufactured by the Ironsides Dyckerhoff Co., of London, England; a complete line of the goods put on the market by the Canadian Buffalo Forge Co.; structural steel work of all kinds; mosaic tile flooring, and many other lines.

LONDON, ENGLAND. — The number of Canadian companies which are extending their businesses in the United Kingdom continues to increase. Owing to Lloyd George's "Trade Mark Act" Canadian possessors of patents must manufacture in the United Kingdom to take advantage of the protection afforded them. This is the reason which decided the Dominion Register Co., of Toronto, to build a plant here.

SWAN RIVER, MAN.—It has been announced that the C. N. R. will build a new steel bridge over the river here, the estimated cost being over $20,000.

FORT WILLIAM, ONT.—The Joint Street Railway Co. favor the establishment of a car works at the head of the lakes, and a report will be made on the proposal. There is some doubt whether the two cities should engage in the manufacture of cars.

QUEBEC, QUE.—The Traction Cultivator Co., of Gainesville, Ga., propose establishing a plant here; as also does a Detroit automobile firm, represented by W. H. C. Burnett, of Detroit.

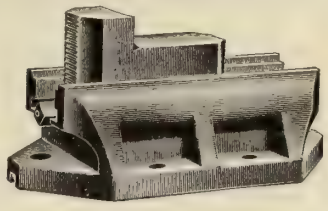


QUEBEC, QUE.—The St. Lawrence Car Co. are seeking to obtain the balance of the capital necessary to establish their plant here.

ST. JOHN, N.B.—It is rumored that a syndicate, headed by Sir Henry Pellatt, is negotiating to secure control of the five independent nail works in Canada to compete with the two combines already existing. The independent plants are located at St. John, Montreal, Toronto, in western Ontario, and British Columbia, making the strategical position of the proposed combine very strong. It is understood that the Maritime Nail Works is considering an offer to purchase their business at a high figure.

MONTREAL, QUE.—R. Bennett and M. Waller, doing business as "The International Supply Co.," assigned on demand of the W. Bennett estate. Their liabilities are about $3,100, divided amongst 55 creditors. The assets consist of stock, fixtures and tools at the factory, Lagauchetiere St., with unfinished contracts for prism lights, etc.

Two-Jaw Box Chucks



Specially designed for fast, continuous and accurate turret lathe work.

JOSEPH DIXON CRUCIBLE COMPANY
JERSEY CITY, ... N.J., U.S.A.

MEDICINE HAT, ALTA.—The Gordon Nail Co., late of St. John, N.B., are arranging to establish an $80,000 plant here.

SASKATOON, SASK. The International Harvester Co. and the Imperial Oil Co. are both making material additions to their plants here. The latter company will spend in buildings this year $500,000.

RESTOULE, ONT.—C. Roberts has opened a machine repair shop here.

MEDICINE HAT, ALTA.—The Alberta Foundry & Machine Shop Co. propose erecting a plant in this city to cost $10,000. This company has been operating at Three Rivers, Que.

GODERICH, ONT.—The Rice-Knight Co., of Toronto, propose erecting a factory here to prepare the brass fixtures used in their lighting systems.

HALIFAX, N.S.—The Nova Scotia Car Works are making several additions to their plant here. New machinery has been installed in order to increase the output, and a steel underframe department is being added. The wheel foundry is also being enlarged.

VANCOUVER, B.C.—The Western Steel Corporation has purchased 2,000 acres of land with 17,000 feet water-frontage on the Fraser river, and will erect a large steel plant in the course of the next three years, at an expenditure of about $5,000,000. A start will be made on the plant this year, and it is expected to expend $1,500,000 on the first section. It will manufacture articles varying from horseshoe nails to structural steel.

MONTREAL, QUE.—It has been announced here that Vickers' Sons & Maxim have the contract for the floating dry dock to be built here. The plans provide for the construction of a floating drydock with a lifting capacity of 27,000 tons; the establishment of a ship-repairing plant and a mill for the production of steel railway ties, in respect of which they receive from the Canadian Government a subsidy of three per cent. interest on $3,000,000 for a period of thirty-five years. The dock is to be completed and installed by May, 1912, by which time the basin will be ready for its reception.

WINNIPEG, MAN.—It is reported that contracts for additional $2,000,000 construction on the G. T. P. shops at Transcona are to be let shortly.

NELSON, B.C.—The new zinc smelter of A. G. French is practically completed. It will have a capacity of five tons per day. Mr. French will also install a plant at a gold mine near here.

VANCOUVER, B.C.—A plant, which, it is said, will cost $200,000, is shortly to be erected at Port Mann by a syndicate of Englishmen and Scotchmen for the purpose of manufacturing nuts, bolts, fishplates and other railroad material. It is said that at the start it will give employment to at least 100 men.

SAULT STE. MARIE, ONT.—$2,000,000 will be spent improving the "Soo" pulp mill recently purchased by the Lake Superior Paper Company.

PORT ARTHUR, ONT.—C. Curran is establishing a new industry here, to be known as the Lake City Boiler Compound Works, to manufacture a new compound for cleaning the interior of boilers and tubes.

PORT ARTHUR, ONT.—The Western Dry Dock Co. are entering into the manufacture of steam boilers and tanks of all kinds, and are preparing to erect a huge plant here. Orders have also been placed for the equipment, including the latest hydraulic machinery. A boiler works will be one of a notable group of buildings that will be clustered around the dry dock, including foundry, machine shops, punch shed, boiler works and woodworking shop. The foundry and machine shops will be equipped to construct engines and all classes of machinery required on a ship, as well as all the other cast iron work used in shipbuilding. The other shops will be equipped to shape and punch the plates, while the forging shop will take care of all the wrought iron required.

SYDNEY, C.B.—There is a possibility that the Nova Scotia Steel & Coal Co., once they have their collieries at South Bar working in good shape, may remove their iron and steel plant to this side of the harbor. This move would greatly facilitate the handling of its iron ore.

SYDNEY, C.B.—A charter has been granted a company with a capital of $10,000,000 for a shipbuilding plant at Sydney Harbor. Sir Henry Pellatt, Toronto; Gov. J. M. Gibson, C. Ellis, Clyde Bank, Scotland; A. Gracie, Fairfield Ship Co.; A. Cross, Sydney, are the incorporators. The company will carry on business under the name of the British-Canadian Shipbuilding & Dock Co. This move presages a boom in the Maritime Provinces.

MEDICINE HAT, ALTA.—By-laws will be voted upon early this month granting con-

cessions to a foundry and machine shop, and a nail factory.

WINNIPEG, MAN.—The Wortman & Ward Co., manufacturers of pumps and farm tools, have decided to extend their plant here as soon as electric power is distributed by the city. The Vulcan Iron Works are also enlarging their plant.

LONDON, ONT.—The McClary Mfg. Co. are adding a $6,000 warehouse to their plant here.

FORT WILLIAM, ONT.—A large automobile concern are contemplating the erection of a plant here.

SASKATOON, SASK. — The Saskatoon Foundry Co. are branching out in a new direction, namely, the manufacturing of up-to-date well drills, the first of which has been tested at their foundry. These are the first of their kind to be manufactured in this province. The machine drills a six-inch hole several hundred feet deep, and the driving power is supplied by a Fairbanks-Morse gasoline engine, mounted on the front of the outfit.

PORT ARTHUR, ONT.—The Atikokan Iron Co. are contemplating the erection of a foundry in connection with their blast furnace, for the manufacture of pipe.

WINNIPEG, MAN.—Sites have been purchased by the Anthers Foundry Co., of Toronto, the Wortman & Ward Co., and the Canadian Carbon Co., for the erection of three more large factories in Winnipeg. The Anthers Foundry Co. has purchased a four-acre site, where a large plant will be erected.

CARLETON PLACE, ONT.—H. W. Dummert and W. H. Thoms, Jr., of the C. P. R. shops, have received a patent on an invention of their own, a new hub liner for locomotive trucks. The C. P. R. have secured the right to manufacture the device for their own use.

SASKATOON, SASK.—The C. P. R. announce that they are increasing their terminal facilities at Sutherland, and that during the current year they will spend $50,000 for this purpose. This amount will be expended on the extension of their present shops and the round-house. An innovation is the erection of a traveling crane in the freight yards for the convenience of handling heavy commodities, such as steel and stone, which are at present handled by crowbars and other primitive methods.

LACHINE, QUE.—The Dominion Bridge Co. will make a large extension to their already immense works during the coming summer.

MONTREAL—R. J. Levy, manufacturer of oxygen welding process, has removed to new and enlarged premises in Viauville, Montreal. The firm erected a commodious factory, with all conveniences for the manufacture of oxygen and for welding.

Municipal.

SOUTH VANCOUVER, B. C.—The ratepayers have authorized an expenditure of a million and a half dollars for municipal undertakings. Of this sum $300,000 is for the waterworks, and $260,000 for erecting new schools, etc. Over a million dollars will be spent on road and street improvements.

WINNIPEG, MAN.—It has been announced here that the Government Elevator Commission will acquiesce to the demand of the grain growers and put in a full complement of modern machinery at all of the Government elevators.

TORONTO, ONT.—The city has set apart $5,000 to secure detailed plans and specifications for a tube system on Yonge Street from the Union Station to St. Clair Avenue.

CALGARY, ALTA.—The estimated revenue of the waterworks department for this year is expected to be in the neighborhood of $163,000; and the expenditure, it is hoped, will be kept well within this figure.

RIDGETOWN, ONT.—This town has practically decided to invest a sum not exceeding $35,000 in a waterworks system. The public feeling is overwhelmingly in favor of the project.

CAMROSE, ALTA.—The Dominion Sewer Co., Swansea, Ont., have secured a $5,000 order from this municipality. Gartshore & Thompson Pipe Foundry, Toronto, secured a contract for cast iron pipes, their tender being $43.20 per ton, and $66 per ton for specials. The tender for valves and hydrants, amounting to $2,028.52, sent in by McAvity & Sons, St. John, N.B., was accepted.

NEW WESTMINSTER, B.C.—A gas manufacturer has a proposition to install a plant here to supply gas at less than current rates. He proposes using mill refuse and selling gas at $1 per 1,000 feet.

MOOSE JAW, SASK.—The ratepayers have passed a by-law authorizing an expenditure of $175,000 for sewer and water extensions, and $50,000 for an incinerator.

PRINCE RUPERT, B. C.—City Engineer Davis has submitted plans calling for an expenditure of $480,110 on a water system.

EDMONTON, ALTA.—J. Cornwall, M.P.P., of Peace River, will pave a street in Edmonton free of cost to demonstrate the paving qualities of asphalt found in the north country. He hopes to show by the test that there is a good field for the asphalt paving industry in the north and to emphasize the necessity of building a railroad up there.

BRANDON, MAN.—A proposition is on foot here to establish a street car system having twelve miles of track and twelve cars.

VANCOUVER, B. C.—The receipts of the waterworks office for the first quarter of the year amounted to $121,821.60. This total is to be compared with $86,769.51, the receipts for the corresponding period last year, neting an advance of over 40 per cent. The receipts for the first quarter of preceding years are as follows: 1909, $75,592.80; 1908, $65,330.16.

EDMONTON, ALTA.—The city council has finally decided upon the terms of the agreement with the International Heating & Lighting Co., of Cleveland, for the local gas franchise. The by-law will be submitted to the ratepayers. The franchise is for twenty-five years, the city retaining the right to purchase. The initial price fixed for gas is $1.65.

NEW WESTMINSTER, B.C.—By-laws totaling over $500,000 were endorsed by New Westminster ratepayers. The by-laws that passed are: Street improvements, $300,000; water extensions $35,000; light extensions $25,000; harbor improvements, $15,000; and garbage system, $5,000; Lulu Island bridge, $30,000; fire hall, $12,000, and the public school by-law, $95,000. The by-law to raise $75,000 for a high school was defeated. The park improvement by-law, $35,000; city stables, $20,000, and the storehouse by-law, $15,000, also failed to carry. It is the intention of the council, however, to erect a storehouse and stable and charge the amount to current revenue.

VICTORIA, B.C.—The cost of the new sewage system for Esquimault will be in the neighborhood of $125,000, which sum will be borrowed from the Provincial Government under the provisions of the District Sewerage Act, 1910, and amendments passed at the recent session of the Legislature.

MONTREAL—It is expected to have all the tenders for the new $2,000,000 water system in shortly and the contracts awarded by the month of June. The specifications are elaborately worked out. They were prepared by Hering & Fuller, the New York consulting engineers, who have made a specialty of filtration systems all over the United States. The double filter system has been recommended.

VICTORIA, B.C.—The city engineer has recommended an expenditure of $290,000 for sewer construction, and an additional $50,000 for drains.

Electrical.

UXBRIDGE, ONT.—F. B. Clark & Co. have taken over the electric light mill here, and the town will now have an all-night service.

BOWMANVILLE, ONT.—The citizens have carried the by-law authorizing the sale of the electric light plant and franchise to the Seymour Power Co. The Seymour exemption by-law was defeated.

OWEN SOUND, ONT.—The C. P. R. liners, Alberta and Athabasca, will have new electric lighting outfits to take the place of the obsolete plants now on these steamships. Two turbine engines will supply the power on each vessel, and will be so arranged as to admit of their being operated coupled or singly. New wiring and switch boards are being put in by the company's electricians and new turbines and dynamos. With the new equipment, these vessels will be brought up to the standard of efficiency the company maintains.

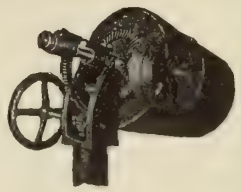
OTTAWA, ONT.—The Government has installed a new electrical apparatus in the Canadian mint, to separate the gold from the dross. The introduction of the electrical process of gold refinement places Canada's mint in a par of up-to-dateness with any mint in the world.

STETTLER, ALTA.—The ratepayers will be called upon to vote $15,000 for the installation of a municipal lighting plant.

NEW GLASGOW, N.S.—The Board of Trade is considering the installation of an electric light plant, with a capacity of 150 h.p.

MONTREAL, QUE.—D. L. McGibbon has purchased the Cedar Rapids. Cedar Rapids are 27 miles from Montreal, and, it is estimated, will generate about 150,000 horse-power, making it one of the largest power propositions in this part of the country.

WINNIPEG, MAN.—The city has decided to strengthen the big retaining walls of the canal of the city power plant at Point du Bois.



GALT, ONT.—The National Electric Co. have moved their plant to Toronto, and will turn out their line of manufactured goods in larger quantities.

LONDON, ONT.—The water commissioners have expended practically all of the $235,000 voted by the people for Niagara power construction purposes in this city. Another $50,000 will probably be required.

WATERLOO, ONT.—To the Town of Waterloo belongs the distinction of being the first municipality in the Niagara power union to pump its city water by Hydro-Electric power. The new electrically-driven pump has been successfully tested.

HAMILTON, ONT.—The Canadian Westinghouse Co. has secured a large contract from the City of Sherbrooke, Que., for an addition to the municipal power plant. The local concern will construct all the generators, switchboards, exciters, etc., and the whole work will cost about $40,000. Sherbrooke already has a good-sized water power plant and the machinery ordered is for an additional power house, which will develop 3,000 horse-power more. The machinery is to be installed in about eight months.

STRATFORD, ONT.—The City of Stratford has been given special permission to amalgamate its light and water commissions to operate the two plants. The by-law to borrow $85,000 for the new Hydro-Electric plant and to take over the electric plant of the Stratford Gas Co. as an extension, has been ratified.

MONTREAL, QUE.—The city has acquired ten acres at Point St. Charles for the purpose of widening the old conduit running to Lachine. This move affords the available water power for the generation of electricity in a new civic power plant to be erected.

WEYBURN, SASK.—The new municipal power plant was put in operation recently. This plant not only develops electricity for power and lighting, but also operates the waterworks pumps.

LETHBRIDGE, ALTA.—The city's electric light and power plant was operated during the year 1910 at a net profit of $30,864.52. The total receipts of the plant for the year were $86,221.30, and the expenditures, including debentures, interest and sinking fund apportionments, $35,356. One of the reasons for the splendid showing made is the operation in conjunction with it of a municipally-owned coal mine. The coal is charged to the electric plant at the rate of $150 per ton, and even at this low rate the mine netted the ratepayers a nice little profit for the year 1910.

BLYTH, ONT.—The Village of Blyth has purchased the electric light plant from the Molsons Bank, and will run it in the interests of the corporation. The price paid was $2,500. J. Nivens continues as engineer.

STRATFORD, ONT.—Stratford is now an all-Niagara power city. The old steam plant that has been used to supply a direct current district up-town is shut down and will be used only in cases of emergency. Hydro-Electric power now runs everything—and satisfactorily.

MONTREAL, QUE.—The council recently revived the question of the city purchasing the plant of the Montreal Water & Power Co. This purchase was a live issue in the council last fall, when the controllers reported very strongly against paying $7,000,000 for the plant. This step was taken on the strength of Mr. Janin's report, in which he estimated the value of the plant as $2,000,000.

FREDERICTON, N.B.—A proposition is on foot here to amalgamate the pumping station and city electric lighting station by the removal of the electric lighting plant, at a cost of $17,000. This would also necessitate the erection of a new building and the enlargement of the boiler-room.

PORTAGE LA PRAIRIE, MAN.—The city council has been negotiating with the Winnipeg council, with a view to getting power from the Winnipeg municipal plant at Point du Bois.

MOOSE JAW, SASK.—The new power house and car sheds for the Moose Jaw Electric Railway Co. will be one of the largest power house buildings in the west, covering a space of 250 by 63 feet. The contract has been given to Navin Bros., of Moose Jaw.

GALT, ONT.—The city has spent $66,000 on Niagara power and will require an additional $25,000 to complete the system.

VICTORIA, B.C.—The city council has decided to make the following purchases of apparatus and plant to carry out extensive additions to the street lighting system: Thirty-five thousand feet of 3-inch fibre conduit, at $7,50 per 100 feet; 50,000 feet of 1-inch galvanized steel conduit, at $8.40 per 100 feet. Tenders are being called for a supply of 150 cedar poles; 8,000 pounds of copper line wire; 1,000 pounds of flexible arc cable; 1,000 glass insulators; 150 magnetic arc lamps and cut-outs; 450 light transformers, and 1-20 circuit arc switch-board.

BRANDON, MAN.—An order has been placed by the Brandon Electric Light Co. for an

engine, which will add 2,250 horse-power to the present capacity and bring the total up to 5,000. This will make the plant the largest for any city of the same size in Canada. The engine is a cross-compound Corliss and its weight 155 tons. It will require 18 cars to transfer it from Galt here.

STE. PAUL, QUE.—The Canadian Light & Power station will be fitted out in the course of a few weeks. A set of Babcock and Willcocks patent boilers have been put in place, and the steam turbine generator set.

FORT WILLIAM, ONT.—A. L. Farquharson, manager of utilities in Fort William, has informed the Port Arthur council that in order to supply power for the street railway it would be necessary for Port Arthur to purchase a new motor generator, at a cost of $24,000.

HAMILTON, ONT.—The council appointed E. J. Sifton, London, as expert to draw up plans and specifications for a municipal light and power plant.

WEYBURN, SASK.—Weyburn's new electric light plant has been put in commission and is thoroughly up-to-date. The engine and dynamo at the old plant were taken down and removed to the new power house, where they will serve as an auxiliary.

HARROW, ONT.—J. A. Secord has disposed of the Harrow electric lighting plant to Detroit capitalists, who already own the plants in Leamington, Kingsville and Essex. A large power house is to be erected in Sandwich, with which the lighting systems of all these towns will be connected. They will furnish both light and power, giving both night and day service. The new firm have assumed control.

General Manufacturers.

LONDON, ONT.—Hourd & Co., furniture manufacturers, are making extensive additions to their factory here. They have recently given large orders for new machinery, and are making other improvements to their present plant. They are about to install an electric power plant, in addition to their steam power plant, which will be retained.

GALT, ONT.—The Crown Furniture Co. have pulled down their old power house and are erecting a large four-storey brick building, to cost approximately $12,000.

SACKVILLE, N.B.—The Sackville Concrete Limited is the proposed name of a new company, which will undertake the manufacture of concrete blocks for building purposes, and other concrete work. The provisional directors are: Dr. Secord, C. C. Avard, S. W. Copp, H. M. Wood and Dr. Hart.

SYDNEY, N.S.—Alex. Cross & Sons, of Glasgow, have closed a contract with the Dominion Iron & Steel Co. for a supply of Bessemer slag, and are building a plant here to manufacture fertilizer therefrom. The home office has appropriated $250,000 for the Sydney end of the business. The plant will cost about $100,000, and already tenders have been called for.

EDMONTON, ALTA.—A $60,000 plant for handling petroleum products, together with all necessary offices and stables, will be erected by the Imperial Oil Co. this spring.

TORONTO, ONT.—The Sunbeam Incandescent Light Co. propose extending their plant on Dufferin Street.

SARNIA, ONT.—It has been reported that the American Brewing Co. intend locating a branch in Canada, and negotiations are under way to bring the plant here.

SARNIA, ONT.—The Sarnia Fence Co. have prepared plans for an extension to their factory.

OTTAWA, ONT.—The McFarlane, Douglas Co. are building a new factory for the manufacture of fireproof doors and windows.

ST. JOHN, N.B.—Experts from the Linde British Refrigeration Co., of Montreal, have inspected the cold storage plant recently taken over by the C.P.R. from the N. B. Cold Storage Co., and have recommended extensive alterations and repairs, involving considerable expense.

GODERICH, ONT.—Fire caused $50,000 loss to the plant of the Kensington Furniture Co recently.

St. JOHN, N.B.—The Albert Manufacturing Co. will erect a $100,000 plaster mill in Hillsboro, to replace the one recently destroyed by fire.

WINNIPEG, MAN.—Winnipeg will see nine new factories erected on Logan, Higgins and Henry Avenues, at a cost of $500,000. A site has been purchased by a well-known manufacturing firm, where a factory will be erected, at a cost of $50,000. A few blocks from this the warehouse and factory of the Ontario Wind Engine & Pump Co. has been completed, at a cost of $50,000. One block east the Burrage Copper Co. will have warehouses and offices erected before the beginning of June. This building will cost a similar sum to the other two mentioned above. Additions will be made this summer by the Imperial Oil Co. to their plant. The Canadian Baggage Co. also intends spending $15,000 on improvements. The wooden building used at present by the Copp Sons & Co. will be replaced by a brick structure. Five lots have been purchased by the Provincial Government on Bushnell Street, where a $25,000 warehouse is to be erected. It is understood that the Czerwinski Box Co. will add two more storeys to its present building, at a cost of not less than $75,000. The Gordon, Ironsides & Fares will spend $85,000 on enlarging its plant. It has been learned that the Coast Lumber Co. will maintain a yard in this district, which will have 8,000,000 feet of lumber on hand, and sheds for the teams.

PORT ARTHUR, ONT.—F. H. Keefer, K.C., who has returned from England, states that British capitalists will probably establish a huge meat packing industry at Port Arthur, in which they would invest $7,500,000. The new company would expect to get large contracts for supplying meats to the British army and navy.

SOUTH VANCOUVER, B.C.—A party of English capitalists are establishing a large enamel works here. They will turn out all kinds of enamelled ware from signs to kitchen utensils.

WINNIPEG, MAN.—Brown & Vallance, architects, have prepared plans for a four-storey warehouse here for the Canadian Fairbanks Co.

TORONTO, ONT.—A factory for the manufacture of laces in this country is being contemplated by a large Irish firm. W. W. Figgis, Dublin, is representing them.

SYDNEY, C.B.—The Dominion Tar & Chemical Co. has about completed an addition to its plant, which will enable it to do creosoting work. Creosoting greatly increases the life of timber in such forms as telegraph poles, railway ties, and piling.

BROCKVILLE, ONT.—The National Mfg. Co. purpose making extensive enlargements to their plants here. In an effort to concentrate their entire plant in this city, they will spend some $20,000 on new buildings.

PATENT NOTICE.

TAKE NOTICE that the undersigned are prepared to supply, at a reasonable price, stone breakers described in Canadian Patent No. 118,289, or to grant anyone desiring to us the same a license to have the same manufactured for him at a manufacturing establishment in the Dominion of Canada. They are also prepared to receive offers for the purchase of the patent or for licenses to manufacture and sell under the same. — Ridout & Maybee, Manning Chambers, Queen Street West, Toronto, attorneys for Emil Barthelmess. MANUFACTURERS OF

THE "SWIFT" MARINE ENGINE

BRIDGEBURG, ONT.—The Flanders Manufacturing Co., of Buffalo, have secured a factory here and will manufacture a great variety of showcases and patent devices, such as collapsible bookcases, mailing cases, etc.

SASKATOON, SASK.—B. F. Ward, of Minneapolis, proposes establishing a factory here to manufacture the by-products of flax straw, to be used in connection with the newly-invented Ware binder—the only arrangement that has been successful in solving the problem of the utilization and the tying of flax cord in the process of binding.

NEW LISKEARD, ONT.—Through the efforts of Mr. McLelland, Toronto capitalists will likely establish a large woodenware industry in this vicinity.

MONTREAL, QUE.—W. H. Bell, who purchased the factory buildings of the Bell Telephone Co., has had the premises refitted with modern machinery and now has the largest woodworking plant in Canada.

VANCOUVER, B.C.—The establishment of a number of plants from the Atlantic to the Pacific is contemplated by the Associated Portland Cement Co., of London, Eng. The plans involve an expenditure of millions of dollars in the Dominion.

PETROLEA, ONT.—The Shuttleworth Co., tile manufacturers, are contemplating an addition to their present plant.

MEDICINE HAT, ALTA.—A by-law was carried here granting a free site to the Alberta Linseed Oil & Paint Co., which will invest $80,000 in plant and buildings.

WINNIPEG, MAN.—The Canada Cement Co. intends establishing a plant here, with a capacity of 400,000 barrels per annum.

TORONTO—The Reinhardt Brewing Co. will build a new brewery on the corner of Mark Street and Don Esplanade. It will have three times the capacity of the present building and will cost in the neighborhood of $150,000.

RIDGEVILLE, ONT.—A large canning factory is being erected here for an incorporated company represented by A. W. Crow, of Fenwick.

TORONTO—The Aluminum & Crown Stopper Co. are erecting a large addition to their works here.

NEWCASTLE, N. B.—J. W. Miller and a St. John promoter are organizing a joint stock company to erect an extract works and tannery here. This will entail an expenditure of $125,000. Mr. Miller has attained a high position as an inventor and will introduce in the works a most successful invention of his own, which machine will tend to facilitate the manufacturing.

OWEN SOUND, ONT.—On May 6th the citizens will vote on three factory by-laws, viz., a knitting factory, a furniture factory, and a baby carriage and steel wheel factory. Two Toronto manufacturers are looking for a brass and iron bedstead factory site. They will probably ask a $20,000 or $25,000 loan, with the usual stipulations as to payment of principal and interest.

Building Notes.

TORONTO, ONT.—Knox College will erect buildings this year to cost $500,000.

TORONTO, ONT.—The plans for the sixteen-storey office building of the C.P.R. have been completed by Architects Darling & Pearson. The building will be of steel, and granite will be used for the walls of the lower storeys. It will be the tallest commercial building in the British Empire.

CALGARY, ALTA.—Harrod's Stores, London, Eng., will erect a building at Calgary, at an expenditure of $1,500,000. Burke, Howard & White, Toronto, are the architects.

WINNIPEG, MAN.—The new C. N. R. terminal will cost in the neighborhood of $5,000,000. The station, which has elevated tracks, covered subways to all platforms and quarters for immigrants, will be opened in July.

TORONTO, ONT.—The R. S. Williams Co. will erect a 10-storey building of reinforced concrete and steel, to cost $75,000.

QUEBEC, QUE.—The new plans for the Union Station, on the Champlain Market site, call for a $1,500,000 structure, which is somewhat larger than at first intended.

TORONTO, ONT.—The Boston Lunch are considering the erection of a six-storey building on Yonge Street, near Richmond.

TORONTO, ONT.—On the corner of Bloor and Avenue Road, W. S. Dinnick is contemplating the erection of a modern apartment house, to cost in the neighborhood of $600,000, exclusive of the site. It will be nine or ten storeys high, of brick and steel skeleton, and thoroughly fireproof.

VANCOUVER, B.C.—The Sailors' and Loggers' Institute are undertaking the erection of a $100,000 building here.

EDMONTON, ALTA.—The Edmonton Apartment Houses, capitalized at $500,000, will undertake the erection of several large apartment houses here. The first undertaking will be the erection of a big apartment block on Fifth Street, overlooking the river valley. This block will be five or six storeys high, and will cost nearly $500,000. It will be the most up-to-date apartment house in the west.

VANCOUVER, B.C.—The Exhibition Board will spend $200,000 on buildings this year.

MONTREAL—Ross & McFarlane have prepared plans for a ten-storey hotel, the site of which alone will cost $800,000. It is to be at the corner of St. Catherine and Peel Sts. The bond issue, it is stated, has already been placed, and while the American interests will be considerable, control will remain in Canadian hands.

VICTORIA, B.C.—Plans calling for an expenditure of $80,000 on the new St. John's church have been prepared by Architect R. Wilson.

EDMONTON, ALTA.—The Grand Trunk Pacific will erect a $750,000 hotel here in the near future.

WINNIPEG, MAN.—The Hudson's Bay Company are erecting a mammoth new store on Portage Avenue, to cost, with the site, $2,000,000.

TORONTO, ONT.—The Y. M. C. A. are about to erect a huge building on College Street, at a cost of $375,000, exclusive of the site.

TORONTO, ONT.—This year's building at Toronto University calls for nine new buildings and a heating plant, to cost $2,830,000.

EDMONTON, ALTA. — The Great West Saddlery Co. will erect a 6-storey warehouse here, at a cost of $100,000.

VANCOUVER, B.C.—The Wallace Fisheries, Ltd., have bought the cannery of C. A. Ternan, at Uchucklesat, on the west coast of Vancouver Island, and have prepared plans for a large cold storage plant of 1,500 tons capacity.

TORONTO, ONT.—G. Wright and E. M. Carroll, proprietors of the Walker House, have acquired the Caer Howell hotel property, on University Avenue, and will erect a fourteen-storey hotel, at a cost of $1,500,000.

VANCOUVER, B.C.—A. Davidson will erect a five-storey apartment house here, at a cost of nearly $100,000.

WINNIPEG, MAN.—P. Lyall & Sons purpose erecting a 16-storey building here, at a cost of $1,000,000.

PENTICTON, B. C. — McGaw & Winnett, managers of the Queen's Hotel, Toronto, are interested in a project to erect a large hotel here, at a cost of $100,000.

Harvesting Companies' Merger.

It has been announced that plans for the future expansion of Deere & Co., steel plow manufacturers, involve a merger with twenty-two industrial concerns; the consolidation of which is to have a single ninety-nine-year charter, with a capital of $50,000,000. The consolidation will be known as Deere & Co. Among those included are: Deere & Co., Moline; Deere & Mansure Co., Moline; Moline Wagon Co., Moline; Marseilles Co., East Moline; Kemp & Burpee Co., Syracuse, N.Y.; Dain Mfg. Co., Ottumwa, Iowa, and Welland, Ont.; Fort Smith Wagon Co., Fort Smith, Ark.; Deere & Webber Co., Minneapolis, Minn, and fourteen branch plants and houses, all having separate charters at present. The Canadian end of this merger will be located at Welland, Ont., where the Dain Co. are manufacturing, and it is understood that additional buildings will be erected in the near future on the land recently purchased adjoining the present plant.

Re-Organize Steel Firm.

Montreal.—The directors' board of the Dominion Steel Corporation will be reorganized in view of the recent death of Senator Forget. The Senator was first vice-president. The death of A. F. Dimmock, of New York, will leave another vacancy on the board, which was composed of J. H. Plummer, L. J. Forget, R. Wilson, Sir William Van Horne, Wm. McMaster, Sir Montagu Allan, Hon. G. A. Cox, G. Caverhill, H. F. Dimmock, Senator MacKay, Fred Nicholls, Elias Rogers, Senator McKeen and W. G. Ross.

Sir Wm. Van Horne is slated for the first vice-presidency, and Sir Henry Pellatt, of Toronto, it is rumored, will also have a place on the board.

The Quebec Bridge.

Ottawa, Ont.—The contract for the superstructure of the Quebec bridge has been signed, the amount involved being $9,000,000. A large guarantee has been posted for the carrying out of the contract.

As previously announced, the Dominion Bridge Co. and the Canadian Bridge Co. unite to form a construction company to do the

work, this company being known as the St. Lawrence Bridge Co.

The contractors of the new structure at Quebec agree to have the work completed by the 31st of December, 1911. The first thing to do is to purchase the land and erect new shops, the whole to cost $1,000,000, as no existing plant in the Dominion is sufficient to carry on such an extensive contract. The shops will be in, or near, Montreal, and not in the neighborhood of the bridge site, as has been suggested. The contract for the steel has already been given to the United States Steel Co., of Pittsburg, as the material will be too long for ocean steamers.

$500,000 Brass Merger.

Somerville Bros., brass manufacturers, with a capital of $100,000 and a large reserve, and the General Brass Manufacturing, capital $75,000, have been merged under the name of the United Brass & Lead Co., of Toronto, with a capital of $500,000. The promoters of the new company are: Alex. F. Fuller, of Chatham; Fred Somerville, Toronto; Murray James, Woodbridge; Lorne M. Somerville, and Andrew J. Somerville, of Toronto.

This new consolidation is outside anything in hte shape of a merger that is being attempted from Montreal. Efforts to absorb those two concerns were made a year ago, but met with failure. Brass manufacturers declare that there is nothing in the mooted merger so far as Toronto houses are concerned.

Saw and Planing Mills.

SOUTH ROXTON, QUE.—Wollet's saw mill, which sustained a serious loss by fire recently, is being rebuilt.

EBURNE, B.C.—The Eburne Saw Mills have been greatly enlarged. The old 100 h.p. engine has already been replaced by a 150 h p. engine of the latest design, while a new engine has been installed in the planing room. In addition, an extra saw is being set up to further increase the capacity.

RENATA, B.C.—P. Abrams has installed an up-to-date sawmill here, with a capacity of 15,000 feet per day.

BROCKVILLE, ONT.—The Briggs' mill was badly scorched by fire recently, due to defective wiring. The loss is fully insured

NEW WESTMINSTER, B. C.—Work has been started on the new mill of the British-Canadian Lumber Co., at Lulu Island. It is strictly electrical, and includes a box factory. Later on a sash-door factory will be added.

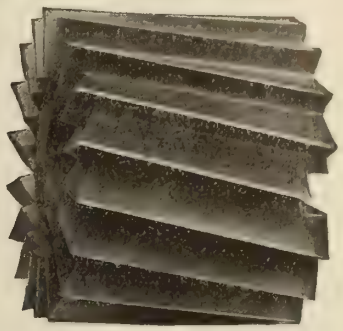
GALT, ONT.—P. W. Gardiner & Son have disposed of the retail lumber end of their business and will now devote their whole attention to manufacturing their specialty—doors, sashes and columns.

SARNIA, ONT.—The prospects of having a new sash and door factory located here are exceedingly bright, and a large amount of money has been subscribed towards the enterprise. A. H. Diver, of Trenton, has invested $25,000.

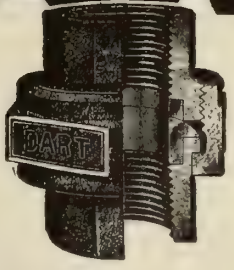
REVELSTOKE, B.C.—Following a recent heavy investment of British capital, approximating two million dollars, in timber and sawmill plants in Revelstoke district, brought about by A. McRae, T. Kilpatrick and G. S. McCarter, of this city, plans are formulating through a group of American and Canadian capitalists for the exploitation of the water power, pulp wood and timber resources of the district on a large scale. The initial investment of the syndicate involves the erection of a sawmill at Big Eddy, on the Columbia river. The mill will have a capacity of two hundred thousand feet per day and will be the largest plant of its kind in the interior of British Columbia. The power for these establishments will be derived from the rapids of the Columbia river, about three miles north of the city, where a power plant will be installed under the auspices of the same group of capitalists.

MOOSE JAW, SASK.—The Lumber Manufacturers' Yards, Ltd., opened up an up-to-date establishment here recently.

FONT HILL, ONT.—Mr. Beaumont, of Picton, is erecting a planing mill here and will open up a lumber yard.



MARMORA, ONT.—J. Hayne and A. W. Dickerson, manufacturers of staves, hoops and heading, have dissolved partnership.



SUDBURY, ONT.—Casey & Shaw are making numerous improvements to their planing mill here. They will use steam power, instead of electricity, in the future.

STEAMBOAT, B.C.—C. A. Baldwin and his associates will erect a sawmill here to provide the lumber for the buildings to be required in the new camp this summer.

PENTICTON, B.C.—The Penticton Lumber Co. have about completed their big sawmill here. Operations will commence in a few weeks. A pipe and box factory will subsequently be built.

EDMONTON, ALTA.—T. A. Burrows, lumber operator, will install three big mills this summer. One will be located near here, another near Jasper Park, and a third on the McLeod river.

NELSON, B.C.—The C. P. R., which is spending $8,000,000 this year on its Pacific division, will erect a large woodworking shop here for the mechanical department.

PRINCE RUPERT, B.C.—The British-Canadian Lumber Corporation, a $20,000,000 concern, will establish a sawmill and pulp mill here, and a large sawmill at New Westminster.

COBALT, ONT.—"The Cobalt Planing Mills," capital $40,000, have been incorporated to carry on the business of sawmill proprietors, etc. J. Joanisse and F. D. Connor, lumbermen; T. R. Jones and M. T. Culbert, mine managers, and H. Joanisse, carpenter, all of Cobalt.

ROSENDALE, MAN.—R. Stewart's sawmill suffered a $40,000 loss by fire. The engine alone was saved.

CAMROSE, ALTA.—Mr. Charette, of Beaumont, is setting up his sawmill here. This makes the third one in this place.

DRYDEN, ONT.—Recent developments indicate that the Dryden Timber & Power Co. will materially increase the capacity of the pulp mill and abandon the idea of doubling the capacity of the sawmill.

PENTICTON, B.C.—The new mill of the Penticton Lumber Co. is nearly completed. A large drying kiln will also be built, and possibly a pipe and box factory.

GUELPH, ONT.—A bad fire at the mill of Geo. McAllister recently did damage to the extent of $15,000.

CREEMORE, ONT.—Geo. Mustard, Jr., has bought the planing mill at Shelburne and already has possession.

NEW WESTMINSTER, B.C.—The plant of the Pitt River Lumber Co., at Coquitlam, including the sawmill and shingle mills, was damaged by fire recently to the extent of $250,000. Rebuilding will commence as soon as the insurance claims are adjusted.

SASKATOON, SASK.—Cushing Bros., of Edmonton, Calgary and Regina, have decided to built a mill here to manufacture doors, sashes, shop fittings, newels, etc. The boiler house will be of concrete, 34x40. The power will be produced by steam.

SCOTSTOWN, QUE.—The Guelph Patent Cask Co. have started their new veneer mill. It is a little over a year since this company bought out the Great Northern Lumber Mills. They have expended thousands on repairs and reconstruction, and now have the most up-to-date plant in Canada.

New Companies.

MONTREAL, QUE.—The J. Watterson & Co., capitalized at $150,000, have been incorporated, to manufacture and deal in iron, steel, metals, etc. J. Watterson, merchant, of Westmount; E. B. Busteed, King's counsel, C. L. Buchanan and J. Strachan, bookkeepers, and H. A. Daniels, stenographer, all of this city.

TORONTO, ONT.—The Moffat-Irving Electric Smelters, capital $40,000, have been incorporated to carry on a milling, smelting and reduction company, and to manufacture iron and steel, etc. J. W. Moffat, mining engineer, W. H. Garvey and J. A. Rowland, barristers, T. C. Irving and A. Dwyer, stenographers, all of Toronto.

BRANTFORD, ONT.—The Acme Electric Appliance Co., capital $300,000, have been incorporated to manufacture and deal in electrical appliances, apparatus, machinery, etc. G. Brereton, fruit dealer, and O. M. Mackie, promoter, of Hamilton; A. Sheard and L. J. Hastings, of Brantford, and N. G. Patterson, of Cambridge, Ont.

WALKERVILLE, ONT.—The New Dominion Motors, capital $100,000, have been incorporated to manufacture and deal in gasoline engines, etc. A. D. Bowlby, merchant, Windsor; W. Papst, farmer, W. C. Burt, farmer, D. Z. Curtiss, manufacturer, and E. T. Grosvenor, physician, all of Detroit.

KEMPTVILLE, ONT.—The Johnston Foundry Co., capital $40,000, have been incorporated to carry on a general foundry and machine shop business. W. S. Johnston, manufacturer, G. H. Ferguson, barrister, C. Johnston and E. Ferguson, and M. Eligh, stenographer, all of Kemptville.

Heap's High Speed Screwing Machines

fully meet the demand for accurate and durable machines, unsurpassed in quality and containing the latest and best features for convenient operation, and large and accurate output. The perfecting of these machines did not happen at once; it took time and careful experimental preparation. Each of the new features embodied in these Screwing Machines has been under severe service and rigid test for a considerable period.

LET US FIGURE ON YOUR REQUIREMENTS

One of the Strong Points of "AMPHIBIA" Waterproof BELTING

is its universal Adaptability

There is a constant demand for "AMPHIBIA" Belting for

Saw Mills
Pulp Mills
Woollen Mills
Laundries
Brick Yards
Tanneries
Breweries, etc.,

where there is a constant danger of deterioration in ordinary belts through moisture.

"AMPHIBIA"

Belting, being absolutely waterproof, can be used in any and every place where power must be transmitted, and always gives complete satisfaction.

SHAPERS

We would like to have your inquiry when you are in the market, as we believe that we can show you better value for your money than any other Shaper manufacturer in the United States. Every machine, before it leaves our shop, is run under belt for at least a week, and it is therefore sure to be in good working order, and will give satisfaction. We would like to send our catalogue describing the superiority of STEPTOE SHAPERS.
